SUPPLEMENT TO "THE ELECTRICIAN," NOVEMBER 1, 1895.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

VOLUME XXXV.

FROM MAY 3, 1895, TO OCTOBER 25, 1895.

LONDON:
Printed and Published for the Proprietors by GEORGE TUCKER, at the Offices of "THE ELECTRICIAN," Salisbury-court, Fleet-street, E.C.

1895.

INDEX TO "THE ELECTRICIAN."

VOL. XXXV.

General Alphabetical Index.

Italic figures denote that the subject matter is in the "Leading Articles" or in the "Editorial Notes."

A

Absolute Measurement of Electrical Resistance: by Prof. J. Viriamu Jones, 231, 253
Absolute Resistance, *228*
Accidents, (*250-volt Shock*) 39, (*Southwark Bridge*) 73, (*Sardinia-street*) *281*, 269, (*City and South London Railway*) 282, (*Chicago Elevated*) 283, (*Toronto*) 344, *Seattle, U.S.A.*) 443, (*Insurance Law in Germany*) 461, (*Portrush Railway*) 569, (*Transformer Burn-out*) 772
Acetylene, 205, (*Standard*) 443
Acetylene, Gas Light and the Electric Arc, Comparative Studies of: by W. Wedding, 777
ADAMS, GEORGE:
  Hysteresis, Frictional and Eddy-Current Losses in Continuous-Current Dynamos, 319
ADDENBROOKE, G. L.:
  The Telephone Service in England, 513
Air, On the Electrification of: by Lord Kelvin, 57, 723
Alternate Current Dynamo Electric Machines, 189
Alternate Current Electrolysis, Phase Differences in: by W. R. Cooper, 541
Alternators, Armature Reaction in: by Dr. Behn-Eschenburg, 424. (*See also page 407*)
Aluminum Electric Power Conductors, 569
Ammeter, Arc Light, Weston, 554
Ampere, A Neglected Experiment of: by Prof. S. P. Thompson, 51
Analysing Harmonic Curves, A Graphical Method of: by E. Basil Wedmore, 512. (*See also page 507*)

Arc Lamps—
  Beetles and Arc Lamps, 313
  Brush Constant Potential, 226
  Brush-Vienna, 496
  Gülcher Patent, Expiry of, 39
  Gwynne Double-Carbon Photographic, 457
  Horizontal Carbon Projectors, [Pochin] 484
  Inverted Lamps in Worsted Mills, 803
  Projection Lamp, Ross-Hepworth, 822
  Spherical Reflecting Globes, 345
  Two Carbon Lamp Patent in America, 527

Arc, Temperature of, Effect of Pressure on: by W. E. Wilson, 260. (*See also page 247*)
Arc, The Electric: by Hertha Ayrton, 418, 635, 743. (*See also page 407*)
Argon, 145, 282, 737, (*Hodgkins Prize*) 540
Armature Reaction in a Single-Phase Alternating Current Machine: by W. G. Rhodes, 397
Armature Reaction, A Method of Graphically Representing, 525
Armature Reaction, Compounding Dynamos for: by Elihu Thomson, 516. (*See also page 508*)
Armatures, Formulæ for the Heating of, *144*, [Ryan] 163
Armoured Cables, The Kensington Vestry and, *248*
Armoured Mains, Self-Induction of: by J. Whitcher, 573 (*See also page 567*)
Armstrong's (Lord) Experiment, *37*
Asbestos, Magnetic, 314
Atmospheric Electricity, *124*, [Prof. A. Schuster] 113, 149, [Elster and Geitel] 599, [Lord Kelvin] 57, 723
A. T. *v.* B. T. Controversy, *214*, *311*
AYRTON, HERTHA:
  The Electric Arc, 418, 635, 743
AYRTON, PROF. W. E., and MATHER, T.:
  A Portable Magnetic-Field Tester, 674

B

BARR, J. M., BEETON, S., and TAYLOR, C. P.:
  Wave Form Synthesis, 257, 286
BARR, J. M., BURNIE, W. B., and RODGERS, C.:
  On Some New Methods for the Delineation of Alternate-Current Wave Forms, 719

Batteries (Primary)—
  Clark Cell, A Portable, [Carhart] 844
  Gassner Dry Cell, Internal Resistance of, 2, [Carhart] 18
  Grove Cell, Action of Nitrous Acid in, *537*, 542
  Levetus Battery, The, *598*
  Standard Cells, Self-acting Temperature Compensation, [A. Campbell] 601

Batteries (Secondary)—
  Bidard Battery, *312*
  Economy and Accumulators, [E. W. Cowan] 222
  Electro-Chemical Reactions in Secondary Cells, [Cooper] 290
  Galvanic Elements, On the Resistance of, [Schoop] 187
  Improvements in Accumulators, 778
  Insulation Resistance, Simple Method of Measuring, [Jacob] 855
  Kowalski Accumulator, *508*
  Persulphuric Acid, Formation of, *407*, 426
  Pellon "Corrugated Plate" Patent, Expiry of, 599
  Storage Batteries, [Earle] 685. (*See also page 664*)
  Swan "Grid" Patent, Expiry of, 111
  Telegraph Work, Accumulators for, 344
  Theric Oblasser Battery, (*Switzerland*) 248, (*Germany*) 598
  Uses of Accumulators, [Howell] 224
Beetles and Arc Lights, 313
BEHN-ESCHENBURG, Dr. H.:
  On the Investigation and Design of Alternate-Current Dynamos, 424
Belt and Rope Transmission Trials, *10*, 15
BENNETT, A. R.:
  Some Lessons in Telephony, 689
BIDWELL, S.:
  Electrical Properties of Selenium, 397 557
Bismuth, Electrical Behaviour of at Low Temperatures: by Profs. Dewar and Fleming, 612. (*See also page 598*)
Bitumen Insulated Cables, 772
BLONDEL, A.:
  Street Lighting by Arc Lamps, 846. (*See also page 850*)
Board of Trade, (*Purchase Clause*) *109*, (*Revised Rules*) *143*, 164, *177*, *213*
Boiler Repairs, Electric Welding in, 269
BOISTEL, E.:
  The Invention of the Electromagnet, 652
BOWDEN, F. W.:
  An Electromagnetic Effect, 397, 555
Brewery Plants, 39
Brighton as an Electrical Town, *37*

British Association—
  Arrangements for Ipswich Meeting, 539
  Electrical Section, Proposed, *701*
  Future Meetings, 665
  Grants, 703
  Harcourt's (Prof.) Presidential Address to Section G, 675. (*See also page 629*)
  Hicks' (Prof.) Presidential Address to Section A, 683. (*See also page 629*)
  List of Papers Read, 681. (*See also* Appendix "Scientific Societies")
  Magnetic Unit Suggestions of Electrical Standards Committee, *663*, (*Discussion*) 721
  Papers to be Read, *597*, 599
  Presidential Address, 681
  Screw Standards Committee, *703*
  Summary, 679, 718
BROWN, HAROLD P.:
  The Permanent Protection of Underground Pipes from Electrolytic Corrosion, 293
Brush, Thomson Carbon, 284

C

Cable Apparatus, 715, 814, 819
CAHEN, HERMANN:
  Polyphase Motor Calculations, 265
CAMPBELL, ALBERT:
  On Self-Acting Compensation for Temperature in Standard Cells, 601
Canada, Electric Light Inspection in, 3
Carbon Brush for Low Potential Machines, Thomson, 284
CARHART, Prof. H. S.:
  Variation of Internal Resistance of a Voltaic Cell with Currents, 18
CARTER, E. TREMLETT:
  Motive Power and Gearing, 5, 147, 217, 315, 514, 820
    Engine Testing, 217, 315
    Gas and Oil Engines, Classification, 820
    Hornsby Engines, 147
    Parsons Turbine, 5
    Steam Engine in Relation to Electric Power, 514
Catalogue of Scientific Papers, International, *408*, 409
Catalogues, Filing, *802*
Cathode Rays, 179

Central Stations—
  Belfast, 410
  Boston Edison Station, Coal Consumption of, 577. (*See also page 568*)
  Brussels, 355
  Budapest, 427
  Coal-handling, *735*
  Coatbridge, 852
  Gare de Sceaux, 219
  Leicester, 14
  Londonderry, 587
  Morecambe, 752
  Salford, 538
  Sheffield, 45
  Smoke Abatement Devices, *537*
  Superheating, *835*
Charge, Rate of Loss of, in Bad Conductors, 181
Circuit Tester, Weston, 235
Civil Engineers, Institution of, 146, 178, 313, (*Subjects for Papers*) 600
Clutch, Holden Magnetic, 457
Coal-handling in Central Stations, *735*
Coast Defences, Electrical, 598
Colour Vision, 379
Condenser, The Charging of a: by Alfred Hay, 840
Contact Resistance of Metals, 4
COOPER, W. R.:
  Alternate-Current Electrolysis, 842
  Electro-Chemical Reactions in Secondary Cells, 290
  Phase Difference in Alternate Current Electrolysis, 541
Compass Indicator, Prize for, 3
Condensers, Commercial Use of, 236, 313
Condensing Water Cooler, Klein's, 271
Copper, Thermal Conductivity of, 569
COWAN, ED. W.:
  Economy and Accumulators, 222
Cranes (*Workshop*) 353, (*Jib*) 844, (*Travelling*) 807
Crewe Works, Electricity at, 7
CROCKER, F. B.:
  Electric Power in Factories and Mills, 488
Curves, Influence of Shape of, on Iron Losses; by C. P. Feldmann, 809. (*See also page 801*)

D

Degrees, Engineering, *522*
DELANY, PATRICK B.:
  High-Speed Cable Signalling, 446
  The Struggle between Telegraph and Telephone, 757
DERR, LOUIS:
  An Apparatus for Measuring Difference of Phase between Alternating Currents, 491
DEWAR, Prof. J.:
  Scientific Uses of Liquid Air, 361
  Thermo-Electric Powers of Metals and Alloys between the Temperatures of the Boiling Point of Water and the Boiling Point of Liquid Air, 365
Diaphragms, The Resistance of, 180
DIEUDONNÉ, EMILE:
  Gare de Sceaux Central Station, 219
DOBROWOLSKY, M. VON DOLIVO:
  Rotary-Current and Alternating-Current Dynamos of the Allgemeine Elektricitats-Gesellschaft, 91
Dockyards, Electricity in, 189
Draft, Automatic Control of Forced, 839
"Drehstrom" Work. (*See* Polyphase)
Drilling by Electricity, 313
Durability of "Asphalte" Cables, 409
Dynamos, The Heating of; by Ernest Wilson, 781

E

EARLE, H. A.:
  Storage Batteries, 685
Education, Research in, 40
Electrical Engineers, Institution of, (*New Members*) 3, 72, 145, (*Past Session*) *454*
Electrical Trade Section, 167
Electric Discharge Through Gases: by Prof. J. J. Thomson, 199. (*See also page 178*)
Electric Lighting Notices, *377*

Electro-Chemistry—
  Alkali and Bleach, Electrolytic, Cost of Production of, 186
  Alternate-Current Electrolysis, [Cooper] 541, 842
  Brass, Electro-deposition of, 613
  Chlorate of Potash, Production of, 509

Digitized by Google

Electro-Chemistry (*continued*)—
Chloride, Alkaline, Electrolysis of, 738
Copper Refining, Electrolytic, in North America, 856
Cuprous Chloride Solutions, Electrolysis of, 89
Electro-Chemical Reactions in Secondary Cells [Cooper], 290
Electro-Chemistry, Recent Advances in, 197
Electrolytic Apparatus, Efficiency of, 496
Electromotive Force, Expenditure of, in Electro-chemical Processes, 617
Gases Dissolved in the Electrolyte of a Silver Voltameter, Influence of, 557
Gases, Heated, Electric Conductivity of, 599
Gases, On the Electrolysis of, [J. J. Thomson] 578. (*See also page 582*)
German Electro-Chemical Society (Frankfort Meeting), 215, 249
Gold and Silver Electrolytic Parting of, 540
Hargreaves-Bird Electrolytic Cell, *837*
Hermite Process at Ipswich, [Napier] 759
Hydrochloric Acid, Electrolysis of, Without a Porous Septum, 234
Indirect Electrolysis, 480, 528, *537*, 559
Iron, Pure, Preparation of, by Electrolysis, [Hicks and O'Shea], 843
Mercury and Copper, Valency of, in Certain Electrolytes, *378*, 381
Milk, Electrolysis of, *735*, 749
Nitric Acid in the Grove Cell, Conditions Governing Action of, *537*, 542
Persulphuric Acid, Electrolytic Formation of, *407*, 426
Thermo-Chemical Data, Electromotive Force from, 180
Zinc Works, 112
Electrodynamometer, Zickler Universal, *71*, 76, *213*, 237
Electromagnetic Theory: by Oliver Heaviside, 41, 182, 252, 346, 481, 571, 666, 739, 805
Electrometer, Hallwachs Improved, 760
Electrostatic Discharge, 343
ELLINGTON, E. B.:
Notes on Hydraulic Power Supply in Towns, 485
ELSTER and GEITEL:
Dependence of the Photoelectric Current upon the Azimuth and the Angle of Incidence of the Light, 272
Embankment, The Lighting of, *408*, 409, 428
Energy, Modern Views on, 313
Engines, *52*, [Prof. Unwin] 46, 77, (*Bills in Parliament*) 111, (*Parsons'*) 5, (*Hornsby*) 147, [Mark Robinson] *71*, *158*, 93, 117, 152, (*Laval Turbine*) 249, (*Student's*) 443, (*Raworth, enclosed*) 665, (*Willans: in France*) 715
Ether, Influence of Moving Matters on, 489
Examinations, The Use and Abuse of, 180
Exhibitions, 678, (*Chicago Diplomas*) 509
Expansion Gears, Automatic, for High Speed Engines, 19

F

FELDMANN, CLARENCE P.:
The Influence of the Shape of the E.M.F. Curve upon the Iron Losses of Alternating-Current Transformers, 809
Fire Risks, Electric Lighting Station as, 422
Fires. (*See* Accidents)
FLEMING, Dr. J. A.:
Representation of Periodic Currents by Polar Diagrams, 43
Thermo-Electric Powers of Metals and Alloys between the Temperature of the Boiling-Point of Water and the Boiling-Point of Liquid Air, 365
Variation in the Electrical Resistance of Bismuth when Cooled to the Temperature of Solid Air, 612
Fog Signal, Electro-Automatic, 379
Fog Signalling at Sea, Visual, 736
Fourier Series, Periodic Functions Developed in—The Graphical Method: by Prof. J. Perry, 285. (*See also page 281*)
Furnace, The Electric, (*Commercial Use*) 215, (*Interior of*) 250, (*Spectrum of Carbon from*) 284, (*Temperature*) 300, (*Priority Claims*) 312, (*Electrolytic Forge*) 540, [Ch. Street] 542, *552*, 631, (*Reduction of Alumina*) 570

G

Galvanometers—
A Very Sensitive Galvanometer, *178*
Rowland Reflecting Galvanometer, 773
Shipboard Galvanometers, 300, [Clark & Weatherall] 355, 430, [Sullivan] 370, [Rymer-Jones] 429
Gas Burner, Incandescent, Sale of, 408, (*Intrinsic Brilliancy*) 442, (*Street Vibration*) 444
Gas Engine Electric Supply Stations, 297, (*Belfast*) 410, (*Chicago*) 443, (*Coatbridge*) 852
German Nomenclature, 39
Glow Discharge, Note on the Effect of, on Oxide of Lead: by E. Warburg, 815
Gold Recovery from Sea Water, *736*
GUY, G. H.:
Electric Transmission of Power in Utah, 778

H

Harmonic Analysis, A New Method in: by A. Sharp, 123
Haulage and Hoisting Plant for Wharf, 180
HAWS, H. T.:
Electrical Transmission of Power, with Special Reference to Mining Operations, 389
HAY, ALFRED:
The Charging of a Condenser, 840
Headlights, Electric, for Southern Pacific Trains, 680
Heaters, Efficiency of, 283
Heating, Electric, (*Workshop*) 568, (*Cars: Boston*) 664, (*Cars*) 838, (*Lagrange-Hoho Process*) 344, 540
Heat, New Standard of, Mr. E. H. Griffiths on, 704
Heat, Transfer of, through Plates with Variously Arranged Surfaces: by William G. Walker, 788. (*See also page 770*)
HEAVISIDE, OLIVER:
Electromagnetic Theory, 41, 182, 251, 346, 481, 571, 666, 739, 805
Helmholtz, Memorial Tablet and Monument to, 703
Hermite Process of Deodorising Sewage: by J. Napier, 759
HERROUN, E. F.:
Iodine Voltameter, 122
HICKS, Prof. W. M.:
Some Points connected with the Preparation of Pure Iron by Electrolysis, 843
Hodgkin's Fund Prizes, 510
HOLDEN, FRANK:
Some Work on Magnetic Hysteresis, 327
HOLTZ, W.:
Theory of the Influence Machine with Oppositely Rotating Discs, 384
Honours, 144
HOSPITALIER, E.:
English Internationalism, 395
HOUSTON and KENNELLY:
A Contribution to the Theory of Demagnetisation, 160
HOWELL, J. C.:
Uses of Accumulators, 224
Hydraulic Power Supply in Towns, Notes on: by E. B. Ellington, 485. (*See also page 477*)
Hysteresis, Frictional, and Eddy-Current Losses in Continuous-Current Dynamos: by George Adams, 319

I

Incandescent Gas Burner (*Intrinsic Brilliancy*) 442, (*Street Vibration*) 444, (*Sales*) 408
Incandescent Lamps—
Brook Green Works, 271
High Voltage Lamps, 556
Maxim Patent, Expiry of, 378
Packard Lamps, Tests of, 617
Series Lighting, 55
Swan "Carbon Joint" Patent, Expiry of, 665
India, an Electric Lighting Act for, 283
Influence Machines with Oppositely Rotating Discs, Observations on the Holtz Theory of: by James Wimshurst, 382
Influence Machine, The, with Oppositely Rotating Discs, Theory of: by W. Holtz, 384
Influence Machine, On the Theory of the Wimshurst: by V. Schaffers, 386
Influence Machines, *393*
Infra-Red Rays, Cause of Invisibility of, 738
Invention, A Plea for the Organisation of, *358*
Inventive Faculty a Myth, Is the: by W. H. Smyth, 779. (*See also page 771*)

J

JACOB, E. S.:
A Simple Method of Measuring the Insulation Resistance of Storage Batteries, 855
JONES, Prof. J. VIRIAMU:
Absolute Measurement of Electrical Resistance, 231, 253

K

KELVIN, LORD:
On the Electrification of Air, 57, 723
Kew Observatory, 284
Klein's Condensing Water Cooler, 271
KLEMENCIC, IGNAZ:
An Apparatus for the Demonstration of the Development of Heat in Wires by Electric Oscillations, 812

L

Laboratory of the Electrical Inspector to the City Commissioners of Sewers, 195
Lagrange-Hoho Process for the Electric Treatment of Metals, 344, 540
Launches, Electric, at Copenhagen, 630
Lecture Theatre, The, 427
LEGAL INTELLIGENCE—
Barclay *v.* The New Zealand Electric Syndicate, 431
Binko (H.) and Co. *v.* Leslie, 99
Bocquet *v.* Frank Suter and Co., 273
British Insulated Wire Company *v.* The Prescott Urban District Council, 431, (*Judgment*) 459, (*Appeal*) 528
Bryson *v.* Town Commissioners of Crieff, 205, (*Appeal*) 498
Bryson *v.* Cumming, 133
Carter, Saunders and Co. *v.* Rummens, 99
Clements *v.* Edwards, 432
Consolidated Telephone Constructor and Maintenance Company, (*Chancery*) 528
Corporation of Portsmouth *v.* Edwards, 400
Crossley Bros. *v.* Peel and Others, 99
Dawson *v.* Foster, 431
Direct Spanish Telegraph Company *v.* the Owners of the s.s. "Caloric," 238, (*Appeal*) 399
Edison and Swan United Electric Light Company *v.* Williamson, 338
Edison and Swan United Electric Light Company *v.* Gustav Strauss, 459
Elton *v.* St. Pancras Vestry (*Judgment*) 64
Fell *v.* Whittaker, 273
Fowler *v.* The Chelsea Electricity Supply Company, Landon and Others *v.* the Same, 171
Kirsopp *v.* Hunter and Jack, 273
Martin *v.* The New British Electrical Installation Contractors, 431
LEGAL INTELLIGENCE (*Continued*).—
Muirhead and Others *v.* Commercial Cable Company, 99
Muirhead *v.* National Electric Supply Company, 171, 400
National Electric Engineering Company *v.* Arnold, 431
North Metropolitan Tramways Company *v.* London County Council, 74, 132
Pembroke Town Commissioners *v.* Dublin Southern District Tramways Company, 621, 6 5
Pink *v.* Cambridge Electric Supply Company, 762
Planet Electrical Engineering Company *v.* Railway Clearing House Committee (*Judgment*) 64
Quayle *v.* Caustic Soda and Chlorine Syndicate, 621
Sandon *v.* The Chelsea Electricity Supply Company and Fowler *v.* the Same, 304

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 885. [No. 1. Vol. XXXV.] FRIDAY, MAY 3, 1895. PRICE SIXPENCE.

NOTES.

THE exhibits of electrical interest at the Royal Society's *conversazione* on Wednesday evening, although numerous, comprised, as usual, nothing of startling novelty, unless indeed Prof. GOTCH'S "Malapterurus Electricus" may be so termed. Dr. JOHN HOPKINSON showed his huge mild cast-steel magnet, and it may be permitted to hope that some day time and funds will allow him to show similar magnets of various brands, say from the softest iron up to tungsten-steel, and thus enable us to see with our own eyes the effects of chemical constitution and physical condition upon this interesting phenomenon of the "soaking-in" of magnetism into large masses of magnetic metal. Close at hand the curve-tracers of Profs. FLEMING and HICKS were in close juxtaposition. Dr. FLEMING also showed samples of his well-known resistances, consisting of fine platinoid wire wound longitudinally over porcelain insulators, the ends being kept apart by a spiral spring so that the resistance-wires are kept taut even when expanded by rising temperature. Mr. CROMPTON showed a fine example of his latest form of potentiometer, and upstairs was responsible for an array of electrical cooking apparatus. Prof. AYRTON initiated all comers into the many advantages of his much-discussed "Students' Simple Apparatus for Determining the Mechanical Equivalent of Heat." Prof. EWING was also at work explaining his hysteresis-meter. Close to the latest form of siphon recorder, exhibited by Dr. ALEX. MUIRHEAD, Prof. GEORGE FORBES showed his mechanical analogue of the phenomena of submarine telegraphy, to which we recently referred. Some objects, at first glance not at all unlike Roman remains, were exhibited by Major CARDEW; these, on closer inspection, were found to be sample insulators, incrustations, and wooden-bearers taken from the St. Pancras mains.

AN exhibit which, in spite of the "mephitic vapours" given off, attracted considerable attention, was that of Prof. ROBERTS-AUSTEN. This centre of attraction consisted of an electric furnace as used by Prof. AUSTEN for the melting of chromium, titanium, platinum, and other metals. For the purposes of exhibition, however, iron nails proved nearly as effective as the more precious metals. Prof. AUSTEN'S furnace consists of a fire-clay case containing a magnesia-crucible. Two adjustable carbon-poles pass horizontally into the furnace, and the arc is deflected by means of an electro-magnet right on to the material to be fused. An image of the molten contents of the furnace was admirably projected by means of a lens and mirror on to the screen. Another most interesting exhibit was the platinum electro-pyrometer devised by Mr. CROMPTON, and described by him in his lecture at the Society of Arts, published in our last issue. Major HOLDEN showed some hot wire instruments, the indications of which were magnified and projected on to a screen.

PROF. EWING'S beautiful instrument for the rapid and accurate determination of the hysteresis of iron samples was greeted at the Institution of Electrical Engineers last week with a chorus of praise tempered by a few gentle criticisms, or rather suggestions of criticism. Potential users concurred in hailing the apparatus as the very thing they had long been waiting for, and co-workers in the same field were not stinting in their eulogies. "None but those who have worried over thousands of rings with a ballistic galvanometer, and worked the planimeter until their eyes ached, can know what a boon the thing is," writes one well experienced in the capricious temperament of transformer iron.

SEVERAL speakers hinted at the possibility of eddy currents in the iron sample and brass-clamps vitiating the readings, whilst others, as we ourselves did, thought there might be an appreciable "fanning" effect when the sample was rapidly rotated. Both the objections were, however, conclusively disposed of. Mr. ALEXANDER SIEMENS and other practical men were not, however, easily satisfied that the treatment, viz., punching out, filing, and annealing, to which the sample strips have to be subjected before testing, left them in the same state as they originally were in the sheet. This point, being largely a matter of opinion and experimental skill, was not cleared up quite so satisfactorily as the others, though Prof. EWING'S experience does not lead him to attach very much importance to the objection, provided his recipe is followed, and the sample strips are treated in much the same way as the actual stampings they are intended to represent.

IF the intention of the Government, when acceding to the appointment of a Special Committee to inquire into the telephone service of the United Kingdom, was to secure a public pronouncement in favour of the nationalisation of the telephone service, they have certainly succeeded in their object. After the irrelevancies of the Deputy-Chairman of the London County Council, the Telephone Committee was

Digitized by Google

treated to the Report of a Special Committee of the London Chamber of Commerce, which, though it had much to say about "properly controlled competition," "varying rates for limited services," compulsory working of "unprofitable areas," and other similar desirable things, did not, either in itself or by the mouths of two of its compilers, tell the Telephone Committee how these *desiderata* were to be obtained, except by Government purchase. And so with most of the other witnesses. They were sadly aggrieved, but all their suggested remedies, except State management, were successively disposed of by one or other of the members of the Telephone Committee.

A Bill for facilitating the construction of light railways in Great Britain was introduced by the President of the Board of Trade on Thursday evening last week. This measure cannot be said to have met with a warm welcome. But as most of the opponents of the measure happened to be opponents of the Government, their remarks were no doubt largely based upon the well-known political problem of making out that Codling was the farmers' friend and not Short, a principle which makes it almost as difficult to ascertain the genuine opinions of members of the Legislature as it is to ascertain the real merits of a system advocated by a big American monopolistic corporation. The Bill introduced by Mr. Bryce is nothing more than the legislative embodiment of the suggestions made in the Report of the Conference appointed by the Board of Trade to consider the question. Promoters of light railways will have to lay their schemes before County Councils, and these bodies, if they consider a case has been made out, will have power to authorise such undertakings, the burden of supplying details being left, as is now customary, to the Board of Trade, who will settle, first of all, whether the line is of sufficiently small importance to be authorised without Parliamentary sanction; secondly, under what conditions it shall be worked; thirdly, mode of obtaining land. It is satisfactory to note that the idea of subsidising these undertakings from the national of municipal sources is emphatically repudiated. We agree with the President of the Board of Trade in thinking that the inertia of the agricultural mind in regard to these novel undertakings will probably be overcome, first of all by the construction of one or two such lines by our trunk railway companies, and that afterwards there will be no insuperable difficulties in raising money in the ordinary manner for the construction of other lines. Mr. Bryce has, in our opinion, put the whole question of subsidising in a nutshell. The matter is, as he pointed out, in the stage of experiment. It may ultimately turn out that the making of these lines is so great a public benefit that either the Treasury or the Local Authorities should be authorised to afford pecuniary assistance if need be. But at present no case has been made out to justify such a marked departure from the usual English mode of procedure. The cordial co-operation of landlords and Local Authorities should make these light railway schemes go through, if there is any real life in them. It is to be hoped that electric traction engineers are preparing to press the many advantages or electricity on the minds of our agriculturists.

Although of only theoretical importance, the investigation of Prof. Carhart into the variation of internal resistance of voltaic cells when generating currents, an account of which appears in another column, is of considerable interest. The disturbing influence of polarisation has been eliminated as far as possible by taking what almost amount to instantaneous readings, the cell furnishing current for only very short intervals of time. The experiments upon a Gassner dry cell show a remarkable decrease of internal resistance as the current increases, a similar decrease being shown by other cells. This does not appear to be due to polarisation, for, as Prof. Carhart observes, such would not serve to emphasise, but to diminish, the effect. It would nevertheless seem advisable to test for polarisation by repeating the observations with the levers so placed that the interval of time between closing the circuit and charging the condenser is, say, doubled or halved. Some allowance might then possibly be made for certain cells, if it were found that an error had thereby been introduced. The Gassner cell, in particular, has very little, if any, provision against polarisation, and the variation may be even greater than shown by the figures that are given. A similar set of accurate experiments upon the variation of internal resistance with time, when constant currents, instead of transient, are being generated, would be of greater practical interest. The same apparatus, slightly modified, might serve for the purpose. The investigation would probably show that the value of the internal resistance of a cell cannot be even approximately stated without reference to the current that was flowing at the time of measurement.

If we consider how full of interest submarine cable work is, whether approached from the mechanical or from the electrical engineering, from the practical or from the theoretical side, the technical and descriptive literature of the subject must be judged singularly deficient. We trust, however, that the series of articles by Mr. H. D. Wilkinson, which recommences in the present issue after a lapse of some two years, will do not a little to fill one at least of the many lacunæ in the history and technique of submarine telegraphy. In his former articles Mr. Wilkinson dealt mainly with the equipment and minutiæ of a modern cable-ship, and described some of the better-known vessels, from the old "Monarch" to the "John Pender." The present series will deal with cable tests, cable-laying, and shore-end repairs. We do not know whether experts are under any moral obligation to make their particular corner of knowledge attractive to ignoramuses who happen to live in the world outside, but hitherto writers on cable matters have not shown any outward and visible sign that they recognise any such responsibility. Maze-like diagrams of connections almost worse than those of a central station switchboard and phenomenonly distended equations have a decided tendency to weary anyone but an expert or an enthusiast.

Light Railways Bill.—This Bill was down for second reading last night.

Royal Society.—A Paper on "Alternate-Current Dynamo Electric Machines," by Dr. Hopkinson and Mr. E. Wilson, was down for reading at the meeting of the Royal Society yesterday.

Digitized by Google

Institution of Electrical Engineers.—The following new members were admitted to the Institution at the last meeting:—Member: F. G. Hart. Associates: J. N. Atkinson, H. Brazil, A. E. Hadley, W. H. Nimmo, H. Phillips, S. L. Rhys Price.

The "Gymnote."—Further trials are about to be made with the French submarine torpedo boat "Gymnote." The Commelin and Desmazures accumulators on board this vessel have recently been replaced by those of the Laurent-Cely type.

Personal.—Mr. T. C. Martin has been elected to the post of president of our esteemed American contemporary, the *Electrical Engineer*, and Mr. J. Wetzler has been elected vice-president and treasurer. These changes arise out of the lamentable death of Mr. G. M. Phelps, which we recorded in our last issue.

Leicester.—It may interest out readers to learn that Mr. Alfred Colson, M.Inst.C.E, who has been responsible for so many details of the Leicester electric supply station, is the President of the Incorporated Institution of Gas Engineers, and examiner in "gas manufacture" at the City and Guilds of London Institute.

Proposed Electrical Utilisation of the Water Power of the Nile.—Mr. Prompt, inspector-general of Egyptian Railways, proposed, at a recent meeting of the Egyptian Institute, a scheme to electrically employ the water power of the Nile to the extent of 40,000 H.P.

Cable Interruptions and Repairs:

	Date of Interruption.	Date of Repairs.

St. Louis—Noronha	Mar. 12, 1895.	April 25, 1895
St. Vincent—San Thiago	April 5, 1895.	April 25, 1895.
Gibraltar—Tangier	April 24, 1895.	—

Steam Engines (Persons in Charge) Bill.—The Committee on this Bill consists of 17 members—viz., Mr. Allan, Mr. Brunner, Mr. Fenwick, Col. Gourley, Mr. Hardy, Mr. Heath, Sir A. Hickman, Sir E. Hill, Sir B. Hingley, Sir J. Joicey, Sir S. King, Mr. Wilson Lloyd, Mr. Paulton, Mr. Renshaw, Mr. John Wilson (Durham), Mr. Woods, and Mr. Wrightson.

Reduction in Cable Rates.—The Eastern Telegraph Company announce that the rates for messages to Argentine, Uruguay, Paraguay, and Brazil (except Pernambuco) are now reduced to 5s. per word. The Direct United States Cable Company also announce that the rate for messages, viâ Galveston, for Argentine, Paraguay and Uruguay has been reduced from 5s. 9d. to 5s. per word.

Royal Institution.—The annual meeting of the members of this Institution was held on Wednesday, Sir James Crichton-Browne presiding. The annual report of the Committee of Visitors for the year 1894 was read and adopted. The real and funded property now amounts to above £102,000, entirely derived from the contributions and donations of the members and friends of the Institution. During 1894 62 new members were elected.

The "Drehstrom" in Russia.—The Kolomensk engineering works are now being fitted up with an electrical installation, by which the whole works will be driven electrically. There will be in all 34 electric motors of a total capacity of 440 H.P. The generating plant will comprise two "drehstrom" generators of 250 kilowatts, one of 50 kilowatts, and three continuous-current dynamos of 88 kilowatts each for lighting purposes.

City and Guilds of London Institute.—The session 1895-96 will commence in October next, when the courses of instruction in Engineering and Chemistry at the Institute's Colleges will continue, and cover a period of two to three years. Particulars of the entrance examination, scholarships, fees, and courses of study may be obtained from the respective colleges, or from the head office, at Gresham College, Basinghall-street, London, E.C.

The Laval Steam Turbine.—At the *Western Mail* buildings at Cardiff a Laval 5-H.P. steam turbine and dynamo has been put down for experimental purposes by the manufacturers, Messrs. George Thomas and Co., of Manchester. By its means a portion of the new buildings is supplied with electric light. The turbine is running at a speed of 30,000 revolutions per minute, this being reduced by suitable gearing to 3,000 revolutions for the dynamo.

The German Association of Electric Supply Stations.—The annual meeting of the Vereinigung der Vertreter von Elektricitätswerken will be held at Munich on June 25th and 26th, immediately before the meeting of the Verband Deutscher Elektrotechniker. The aim of the Association, which consists at present of representatives of 40 German and four foreign electric supply stations, is to promote the interests of the supply stations by means of reports, statistics and debates.

The Belt Line Tunnel.—A *Times* cablegram, dated Philadelphia, May 1st, states that the Baltimore and Ohio Railway began to send traffic through the Baltimore Belt line tunnel, which has been constructed to facilitate traffic under Baltimore between the north and the Washington tunnel. It is 7½ miles long, and has cost $8,000,000. These trains, as our readers are aware, will be drawn by electric locomotives when everything is completed.

Electrical Bills in Parliament.—On Monday last the London County Council Money Bill passed the Examiners on Standing Orders of the House of Commons. The Bill provides, among other things, £21,000 for the electric lighting of the Victoria Embankment and Waterloo and Westminster Bridges.——The Standing Orders Committee, presided over by Sir John Mowbray, has declined to dispense with the standing orders in order to allow the Great Northern and City Railway to add a provision to their Bill enabling them to use steam in substitution of, or in addition to, electricity upon the line from Finsbury Park to the City.

Dr. von Stephan.—On Friday last the German Emperor sent an autograph letter of congratulation to Dr. von Stephan, Postmaster-General, who celebrated the twenty-fifth anniversary of his appointment as head of the German postal service on Friday last. The whole telegraph system was also placed under his control immediately after the founding of the Empire, and the number of telegraph offices has increased under his management from 1,070 to 13,300. The municipalities of Cologne and Bremen, on Friday last, conferred their freedom upon him. Dr. von Stephan, it is said, had to leave Berlin a few days ago in order to avoid the ovations of his friends.

A Prize for a Compass Indicator.—The current number of the *Elektrotechnische Zeitschrift* contains an advertisement of the German Admiralty offering 3,000 marks (£150) for the best solution of the following problem:—The direction of the compass-card of a ship to be automatically transmitted to any part of the ship, so that a ship can be steered by it. The invention must be suitable for service conditions. The decision to rest with the Naval Secretary of State, who reserves the right to make use of the selected invention for the Imperial Navy without payment to the inventor. Schemes should be submitted to the Reichs-Marine-Amt, Nautische Abtheilung, Berlin, not later than April 1, 1896.

Electric Light Inspection in Canada.—The *Canadian Gazette* announces that by proclamation of the Governor-General of Canada, the Canadian Act respecting inspection of the electric light came into effect on April 1st. Certain formalities have yet to be arranged before the measure will be fully in operation. The work of inspection will be performed by present gas inspectors, without any increase of salary. Under the Act electric lighting companies are required to register. Certificates of registration will be renewable from year to year from July 1st. A special set of inland revenue stamps has been devised as receipts for the payment of inspection fees.

Electric Traction Currents and Physical Laboratories.—The *Elektrotechnische Zeitschrift*, speaking of the interruptions to physical work by electric tramways, says that opinions on this point are still divided, although the question has been repeatedly a subject of discussion. The question, however, requires a speedy solution. For this reason the technical committee of the Elektrotechnischer Verein of Berlin, in conjunction with the Physico-Technical Institute, are making experiments on the matter of earth leakage currents and the changes in the magnetic field caused by electric traction. At

Digitized by Google

the same time current literature is to be searched, and those who have special knowledge of the subject are to be requested to state their experience. It is intended to collect materials for a report on the matter at the meeting of the Verein this month, and it is expected that a large number of experts will record their experience.

Press Telegrams.—Mr. A. Morley, in answer to Sir S. Northcote, said in the House of Commons on Monday last that he had stated on the 4th ult. that he was willing to arrange for an investigation into the loss from Press telegrams if satisfactory assurances were given that the Press would abide by the result, and would undertake not to oppose the necessary legislation for a revision of the charges if it should be shown that they were insufficient. As to the telegraphists, he was not aware that he stated that the telegraph department "must be placed upon a commercial basis." What he did say was that "a great commercial department like the Post Office could not afford to disregard commercial principles"; and he added that he was supported in this view by the report of the Select Committee on the Revenue Departments in 1888, in which attention was called "to the fact that the department of the Postmaster-General in all its branches is a vast Government business which is most likely to continue to be conducted satisfactorily if it should continue to be conducted with a view to a profit as one of the revenue-yielding departments of the State."

Central Technical College.—The following extracts from the 1894 Report of the Council of the City and Guilds of London Institute may prove of interest:—The Council have reason to believe that the change of name has been to the advantage of the College. The total number of regular students is now 222, against 205 in 1892-93. The distribution of students pursuing a complete course of instruction, as laid down in the programme, and attending all four departments during the past three sessions, is as follows: Civil and mechanical engineering course, 71; physics and electrical engineering course, 95; chemical course, 20. The number of students attending the courses of instruction provided for those who intend to follow a chemical career has doubled. The present laboratory and workshop accommodation does not allow of any material increase in the number of students in the engineering and physical departments, but the Council trust that the number entering the chemical department may continue to increase until it also is full. The College was opened to students in January, 1885. There are now in all 150 past students who have gained the Diploma. The Council venture to think that the careers of these amply show that the instruction provided has been such as to fulfil, to the full extent anticipated, the objects for which the College was established. These objects were to give to London a College for higher technical education, in which advanced instruction should be provided in those kinds of knowledge which bear upon the different branches of productive industry; the courses of instruction were arranged to suit the requirements of persons training to become technical teachers, or preparing for higher posts as engineers and chemists.

The Electrical Equipment of the New Post Office at Leeds.—The electrical equipment of the new post office at Leeds, which is now approaching completion, provides not only for lighting the whole of the building by the electric light, but also for putting electrical power to uses to which it has not hitherto been applied in any post office. The boiler house and dynamo room are situated in the basement. Three boilers of the water-tube type will be laid down, each capable of evaporating 3,000lb. of water per hour into steam, at 125lb. pressure per square inch, current is supplied by three Willans-Holmes sets, and the dynamos will each supply 340 amperes at 108 volts. There are to be in all 36 arc and 563 glow lamps, chiefly of 16 c.p. At the four corners of the main building electric hoists connecting the different floors are being erected. The vacuum and pressure pumps of the pneumatic despatch arrangements will be worked by an electric motor. In the new telegraph room several improvements upon existing arrangements are to be introduced, the most important change being the substitution of secondary for primary batteries for telegraph purposes. It is estimated that about 200 secondary cells will be sufficient to replace the whole of the primary batteries. Accumulators will also supply the currents in the large new telephone room, which is being prepared in view of the acquisition of the trunk telephone lines by the State. Some of the rooms in the new building are so far apart as to be beyond the range of the ordinary speaking tubes. Telephones are therefore being fixed in the rooms of the postmaster and heads of departments, in order to facilitate the management of the different branches.

Contact Resistance of Metals.—In the *Comptes Rendus* of the 22nd ult., M. Edouard Branly describes some experiments recently carried out by him in regard to the electric resistance between two sheets of metal in close contact with each other M. Branly employed thin sheets, 48mm. square piled one on the top of the other, and compressed together by a weight of 6 kilogrammes. Electric connection was made with the column by means of sheets of brass at the top and bottom of the pile of plates. When a sheet of zinc was placed between two of copper, the contact resistance was very small and remained constant; but when a sheet of aluminium was placed between two sheets of bismuth, the resistance was quite appreciable and increased with time. Thus, in one experiment, the resistance was, to start with, 0·4 ohm, and 25min. after the contact had been made it was 0·74 ohm, and 5 hours after it was over 3 ohms. If the experiment was varied by putting the sheets of Bismuth together and separating the aluminium from the bismuth by a sheet of brass, there was no appreciable resistance. M. Branly remarks that his experiments show that for certain metals, such as copper and zinc, the surface of contact is not the seat of any appreciable resistance; but for others, such as lead-aluminium, lead-iron, tin-aluminium, tin-iron, bismuth-iron, bismuth-aluminium, &c., there is an appreciable resistance. When the 6-kilogramme weight was replaced by one of 26 kilogrammes, the resistances at the beginning and the resistances as measured later on were smaller, and the same was the case when the pile of sheets was compressed in a vice; but in all these cases a higher resistance was found than one would have expected according to current notions, and this resistance always increased with time. This contact resistance of two metals in air can, M. Branly states, be altered by mechanical shock or by electric spark.

Finsbury Technical College.—The following extracts from the 1894 Report of the Council of the City and Guilds of London Institute may prove of interest:—The eleventh complete session of the day department ended in July last, and the number of students in attendance was 197, as compared with 213 in the previous session. The decrease was due to the smaller number of second-year students in the mechanical and electrical departments, a larger proportion than usual of first-year students of the previous session having failed to obtain promotion to the second-year course; the attendance during the current session has again risen to over 200. There has been a steady increase in the number of students attending the course of instruction in industrial and technical chemistry. The students following the mechanical engineering course number 5, the electrical engineering course 99, and the chemical course, 47. During the year the refitting of the benches in the chemical laboratory, commenced in the previous year, was completed, and has added greatly to the efficiency and comfort of the department. The equipment of the electrical laboratory has been increased by the purchase of the polyphase apparatus used for the transmission of power at the Frankfort Electrical Exhibition. The Mordey alternating dynamo in the electrical laboratory, and the new testing machine in the mechanical laboratory, have proved valuable additions. In the evening department of the College, 1,091 tickets were sold during the session to 922 individual students, as against 1,183 tickets sold in the preceding session to 980 students. The number of tickets taken by apprentices under 20 years of age, who are admitted at half fee on producing their employers' certificate, was 283, as against 359 in the previous session. The decrease in the number of evening students attending the College may be partly due to the influence of the polytechnic institutions in and around London, for it has shown itself mostly in the classes in plumbing, machine design and electric technology.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(Continued from page 757, Vol. XXXIV.)

The Parsons Steam Turbine.—In this country the Parsons, and on the continent the de Laval, steam turbines are, as far as the author is aware, the only representatives of rotatory steam engines in electric supply stations. It is not necessary here to enter into the many and great difficulties which have been encountered in the efforts to develop a commercial rotatory steam engine—though, it is a curious fact thatthe very first recorded engine, that of Hiero, was rotatory—but it may be stated that practically all these difficulties have been overcome, at any rate where high speed is not objectionable, and a thoroughly efficient and serviceable motor has been produced in the Parsons steam turbine.

There are many so-called rotatory engines in which veiled reciprocation of the working parts occurs; but a true steam turbine is that in which the simple rotation of the working parts is caused either by the impulse of a directed jet of steam or by the reaction of its issue from a nozzle or other orifice. In the Parsons engine the effective head of the live steam is distributed in the same manner as the hydraulic head of a drowned turbine; in other words, the action of the steam on the vanes is partially by impulse and partially by reaction. It would be more correct to say, perhaps, that this engine resembles a series of drowned turbines, inasmuch as the steam passes *seriatim* through a number of sets of guide blades and vanes, the latter all being arranged on one shaft. The steam acts during outward, radial flow; and when it has reached the outer edge of one set of revolving vanes it is guided by the fixed blades to the centre again, whence it once more flows radially outward between the next set of revolving vanes.

This will be made more clear by reference to the accompanying illustrations. Fig. shows the 61 elevation and Fig. 62 the plan of a Parsons engine coupled direct to a 100-kilowatt (134 E.H.P.) dynamo, drawn to a scale of ¾in. to one foot. This engine was designed to run at about 4,800 revolutions per minute, with steam supplied at about 100lb. on the gauge; and for a reason which will presently be stated, the steam is usually superheated several degrees. The turbine case is shown at *a*, and contains, in this particular engine, seven sets of vanes, built up of sheet brass. A longitudinal section of the admission end of the turbine is shown in Fig. 63. Steam is admitted through a double-beat throttle valve, which is controlled by the governor; and after admission it passes directly towards the centre until it arrives inside the first set of vanes. By impact and reaction it exerts a torque on these vanes, and glides over their surface and is discharged into the next guide passage, through which it passes to the inside of the second set of vanes. A loss of head—or pressure —and a fall in temperature takes place continuously throughout the vane passages; and finally the steam is discharged into the air or into a condenser at as low a pressure as may be desired.

In order to comply with the conditions of high efficiency it is necessary for the vanes to have a high peripheral speed, and it will easily be seen that for structural reasons this will render a high speed of rotation necessary. On this account it becomes a matter of necessity, when the dynamo is to be coupled direct to the engine, to design a special form of electric generator. The same conditions of high efficiency make it preferable to keep the initial pressure of the steam constant, if the speed is to be constant, rather than to throttle down the initial pressure to suit the load; and this further makes it necessary to reduce the period of admission, as it were, by alternating it with frequent periods during which the valve is closed. The ratio of the admission period to the interval of no-admission which follows will, of course, depend on the load; and it is controlled by the governor. Thus, at light load, the

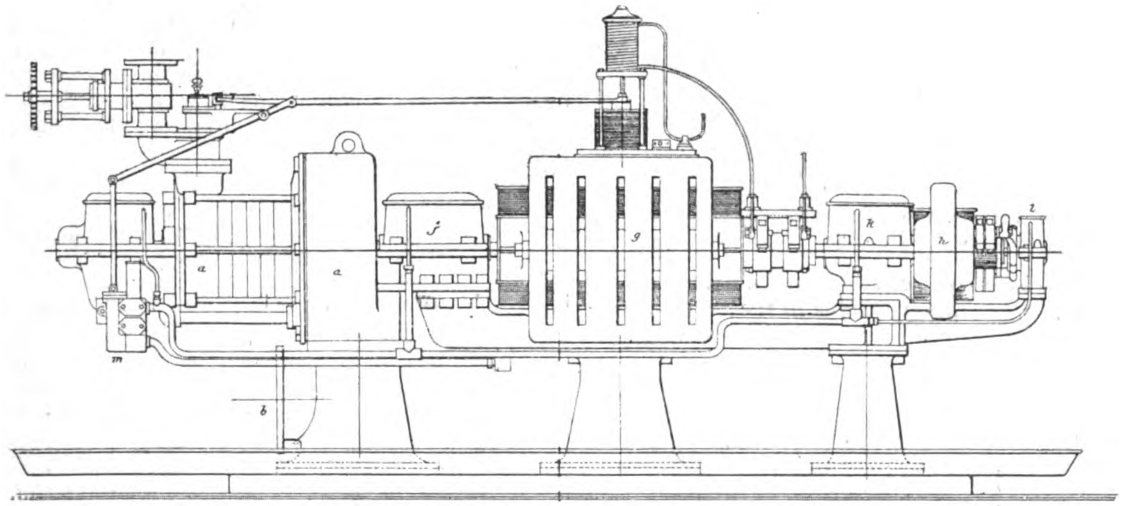

Fig. 61.—Longitudinal Elevation of Parsons Steam Turbine Coupled to 100 kilowatt Alternator. *a* = Turbine Cases. *b* = Exhaust. *g* = Alternator, surmounted by electric governor. *h* = Exciter. *j* and *k* = Bearings. *l* = End Bearing. *m* = Oil Circulation Pump.

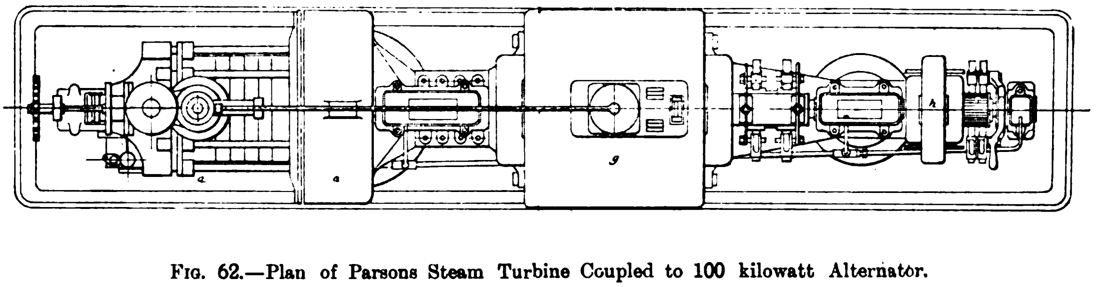

Fig. 62.—Plan of Parsons Steam Turbine Coupled to 100 kilowatt Alternator.

Digitized by Google

steam enters in a quick succession of puffs; at higher load the puffs are more prolonged; and at full load they blend into practically one continuous blast. This is shown clearly in the

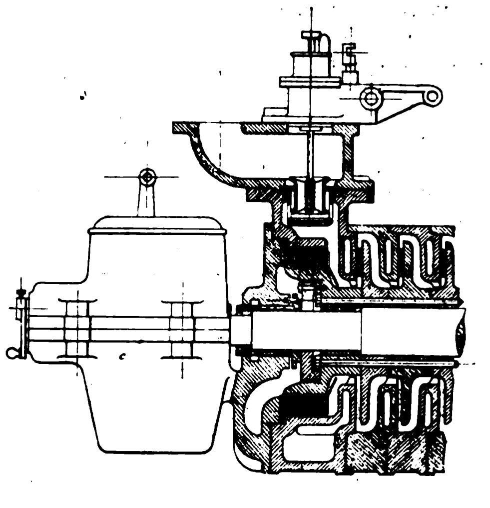

FIG. 63.—Parsons Steam Turbine.—Longitudinal Section of Turbine Case. c = Oil Box.

pseudo-indicator cards of this engine, in Fig. 64. It is not possible to "indicate" a steam turbine in the ordinary way, as there is nothing analogous to "stroke"; but variations

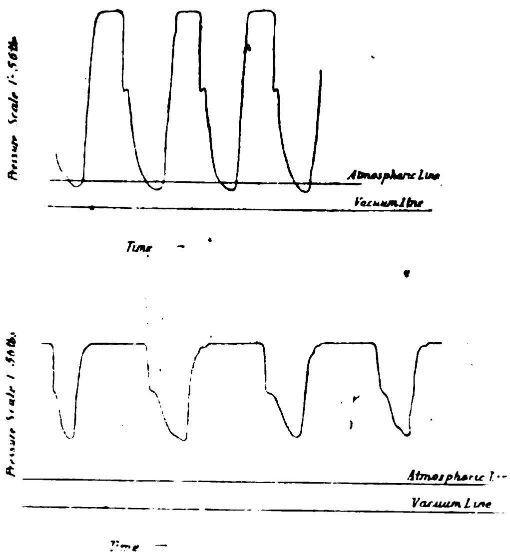

FIG. 64.—Pressure—Time Diagrams of Parsons Steam Turbine.

of pressure may be indicated by attaching an indicator and moving the cord with a uniform speed by hand. The result of this is shown in Fig. 64.

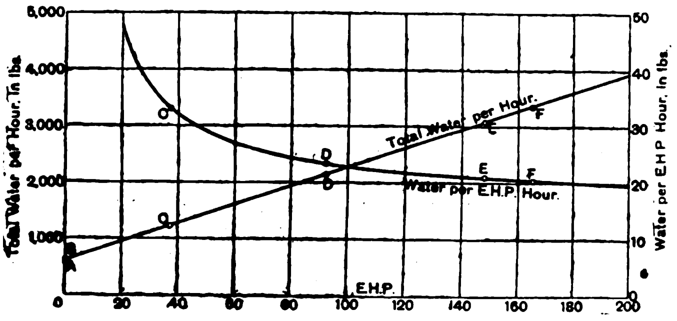

FIG. 65.—Steam Consumption of Parsons Steam Turbine.

In the same sense that it is impossible to "indicate" one of these engines, it is true also that they have no indicated H.P.; but it is convenient to call the rate of total working of the steam on the vanes the I.H.P. Prof. Ewing estimated, in a series of trials which he conducted on this engine—the one shown in the illustrations—that with an electrical output of 100 kilowatts the total power was about 179 I.H.P. The consumption of steam per I.H.P. per hour, at full load, was found to be 15·7lb., measuring the feed water; and at half load, about 17lb. per hour. These figures were based upon the measured consumption of 28lb. per Board of Trade unit of electrical energy, or 20·9lb. per E.H.P. per hour, at full load. The relation between load and consumption follows very nearly the Willans straight-line law; and the idle load was found to be about 36 H.P. The steam was superheated to 400° F., and had an initial pressure of 100lb. on the gauge.

Prof. Ewing's experiments were conducted in August, 1892. By April, 1893, considerable changes in the proportion of the working parts had been introduced into the engine; and at that time another series of trials was conducted by Prof. Kennedy with even more satisfactory results. The engine tested by Prof. Kennedy was of the same size as the previous one, but alterations internally enabled it to develop 150 kilowatts with a steam at 100lb. on the gauge. It ran at about 4,500 revolutions per minute, and it was direct-coupled to a continuous current dynamo. Fig. 65 is taken from Prof. Kennedy's report, and shows the steam economy. Further details of the trials are given in the following table, which is derived from the same source:—

Trials of a Parsons Steam Turbine and Dynamo, by Prof. A. B. W. Kennedy, April, 1893.

Water per E.H.P. hour, lbs....	...	...	32·9	23·3	20·8	20·3	...

There can be little doubt that a great deal of the excellence of these results is due to the use of superheated steam. With wet steam the turbine gives far less satisfactory results, owing to the internal friction developed by the particles of water.

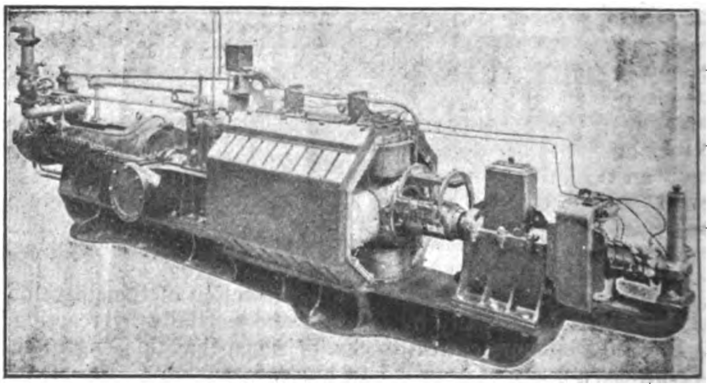

FIG. 66.—Parsons Parallel Flow Steam Turbine and Dynamo.

In this engine there is no cylic change of temperature of the parts, as in a reciprocating engine—except, perhaps, when the puffs are very far apart—and consequently there is not the same tendency to condensation of steam. If the steam is superheated before admission, it will remain dry almost if not

Digitized by Google

quite until the exhaust takes place. In this way the clogging action of the steam is reduced to a minimum, and a high degree of perfection is attained.

Another point in favour of the engine is the absence of vibration from its foundation, due to the absence of reciprocating motion from its working parts. This valuable property has led to its adoption in supply stations where vibration would be liable to cause a nuisance; and in cases where trouble had already arisen from the vibration of reciprocating engines, a solution of the difficulty was found in the substitution of steam turbines.

A recent modification of the Parsons steam turbine is shown in Fig. 66, and has been introduced into electric supply stations. In this engine the steam has a "parallel flow," instead of the "radial flow" which occurs in the earlier patterns.

(To be continued.)

ELECTRICAL PLANT AT THE CREWE WORKS.

It is only by an excursion round such gigantic and varied engineering works as those of the London and North-Western Railway, at Crewe, that one can adequately realise, on the one hand, the extent to which electrical appliances have already been utilised in railway engineering, and, on the other hand, the immense field for their application, which as yet remains quite unapproached. If it is true—and it most certainly is true—that in the phenomena of electricity the railway engineer has found the solution of his most brilliant and ingenious devices, and a means to ends without which modern railway practice could never have come into existence, it is also impressed upon one, when the lines on lines of vast workshops and countless locomotives meet one's eye, that there are still wide areas of engineering practice where electrical science is not even a competitor with older and more mechanical methods of work. In the face of such rivals, electricity will have a hard struggle before it can attain the complete triumphs in railway engineering which some enthusiasts have predicted for it. Not that it can never triumph, but that the progress towards this elimination of older practice must of necessity be but a gradual one.

Already progress has been made, and that not merely in the subtler and lighter engineering work involved in signalling and allied inter-locking of railway plant, but also in the heavy engineering of the workshops, as well, of course, as in railway electric lighting. In the Crewe works many interesting applications of electric power have been made, and we are informed that hitherto great success has attended.

One of the most important of these applications is a 20-ton gantry crane in the boiler shop. This has recently been erected for riveting purposes, and it is most instructive to watch the ease and precision with which the operator, who stands on a raised platform just on the level of the work, can move the boiler about and adjust the plates to the hydraulic riveting machine. On the gantry crane, high overhead, there is no operator, the three motors being manipulated entirely by the man on the level of the work. Everyone who knows anything about boiler-shop practice will appreciate the saving in time and the precision of work thus rendered possible. The man stands with five small levers before him. With four of these he directs the movements of the electric motors in the crane, which moves on longitudinal and transverse rails at a height of 50ft. With the fifth lever he manipulates the hydraulic riveter. The four electrical levers manipulate the three motors—which give the boiler the three degrees of motion—and an electromagnetic brake, by which the work can be instantly locked in place when properly adjusted.

There are several similar gantry and other electric cranes in some of the other shops. One of these, a four-ton crane in the new wheel shop, we are, through the kindness of Mr. F. W. Webb, enabled to illustrate. It is largely to the ingenuity and enterprise of Mr. Webb, the well-known locomotive superintendent of the London and North-Western Railway, that the electrical developments of which we have to speak in this article have taken place, and that others are in rapid progress. The 4-ton electric crane, shown in elevation and plan in Fig. 1, is operated by three small motors, each of which drives through a worm gear. The lifting motor runs at about 1,800 revolutions per minute, maximum speed, and develops about 8 84 H.P. The long traversing motor runs at 1,860 revolutions per minute, and develops about 7·3 H P. The cross traversing motor runs at 1,250 revolutions per minute, and develops about 4·4 H P. These motors are supplied with electric power at 110 volts, through the switching and rheostat gear on the floor level, from the power mains which are carried along the shops. All the other cranes are arranged on practically a similar plan, differing only in the speeds and amounts of power developed.

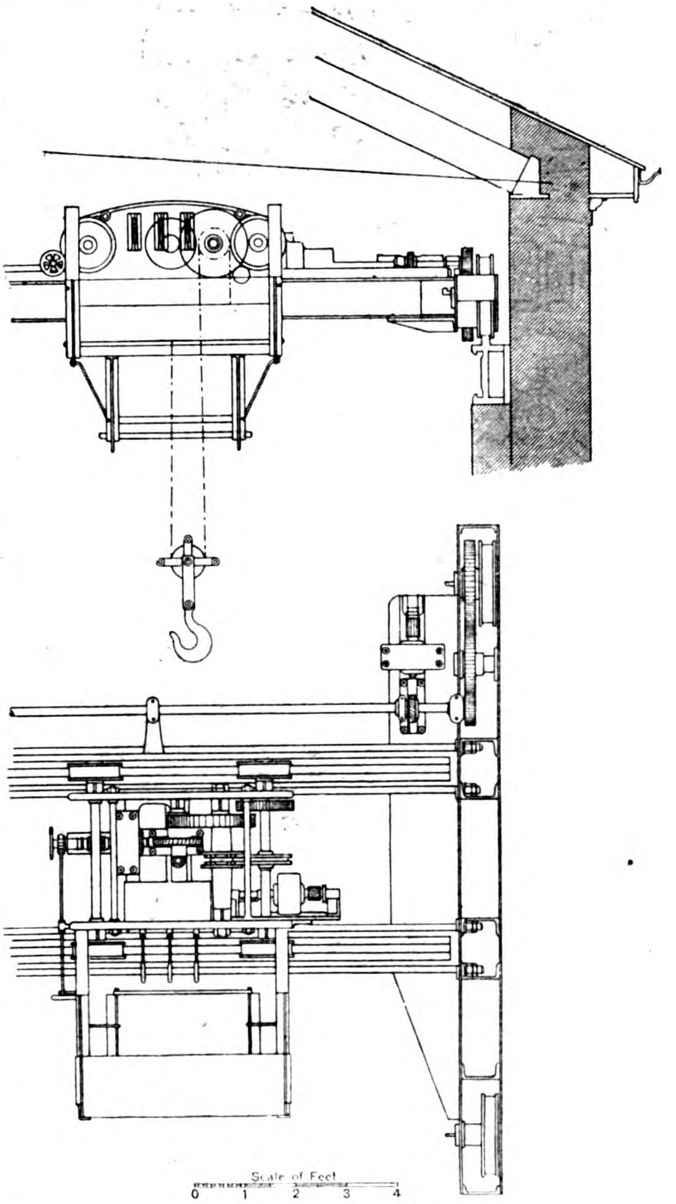

FIG. 1.—4-ton Electric Gantry Crane.

One of the most interesting features of the electrical plant at the Crewe Works is the extent to which the fitting and repairing, and similar shops, are wired for small electric tools, such as tube-cutters and drills. Many of the shops have been wired down the pillars between the bays, so that by means of a piece of flexible cable and a portable plug these tools can be used at various parts of the workshops. We believe it is intended to wire still more of the shops in this manner; and there is no doubt that this ought to prove one of the most useful and facile applications of electric power in these shops.

In our opinion the most ingenious, and perhaps the most useful of the electric machine tools which we saw at Crewe Works, was the "Webb" locomotive tube-cutter, for cutting away the furnace tubes of locomotives under repair and for trimming off

Digitized by Google

the ends of new tubes. The machine is wonderfully light and portable, and it does its work in a manner and with a speed which must vastly astonish anyone who has been accustomed to

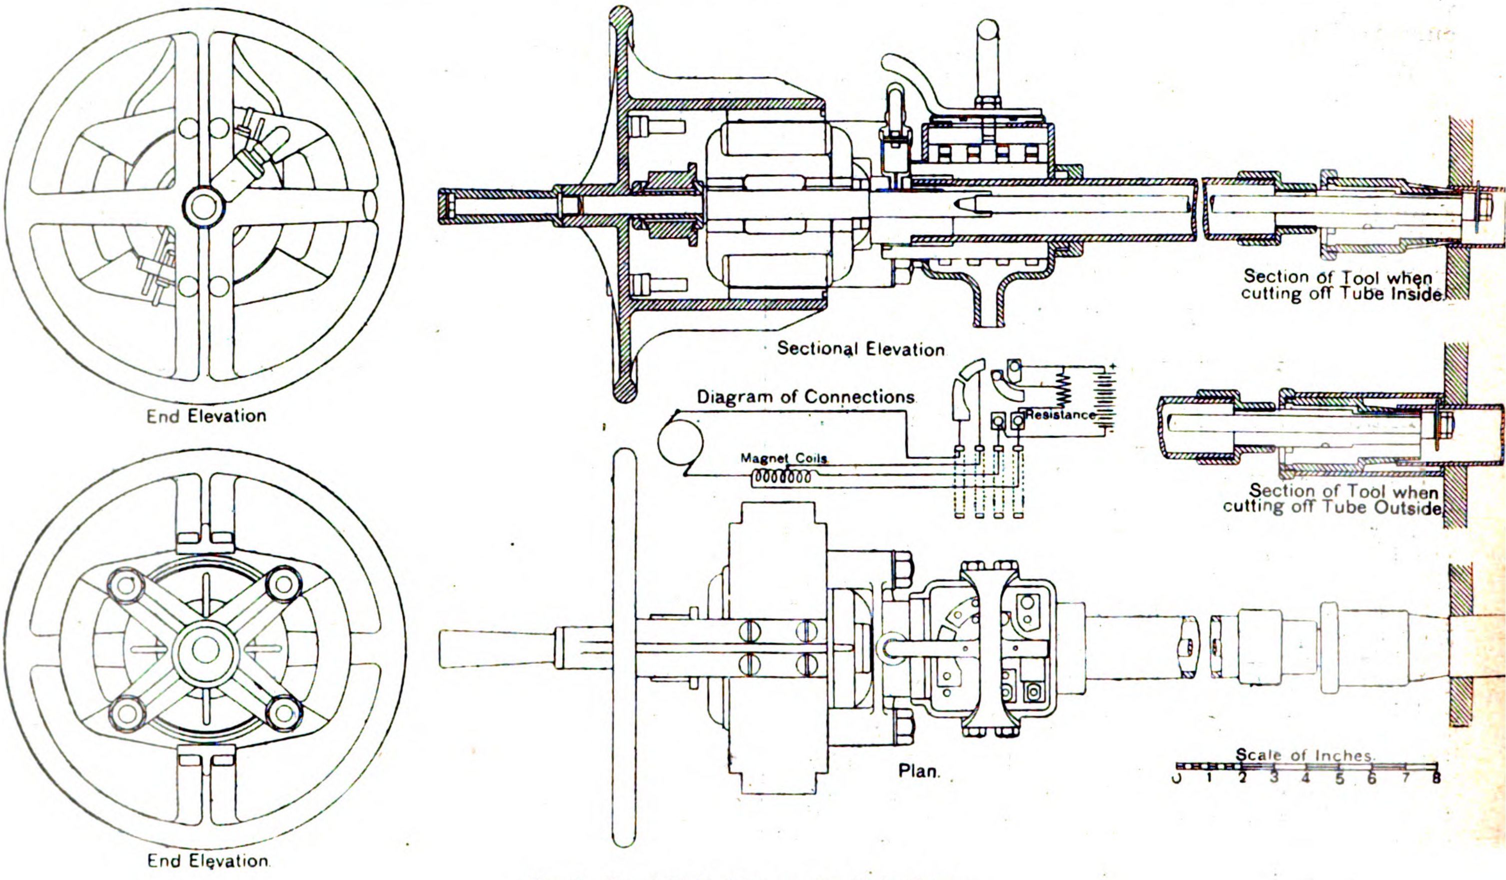

FIG. 2.—The "Webb" Locomotive Tube Cutter.

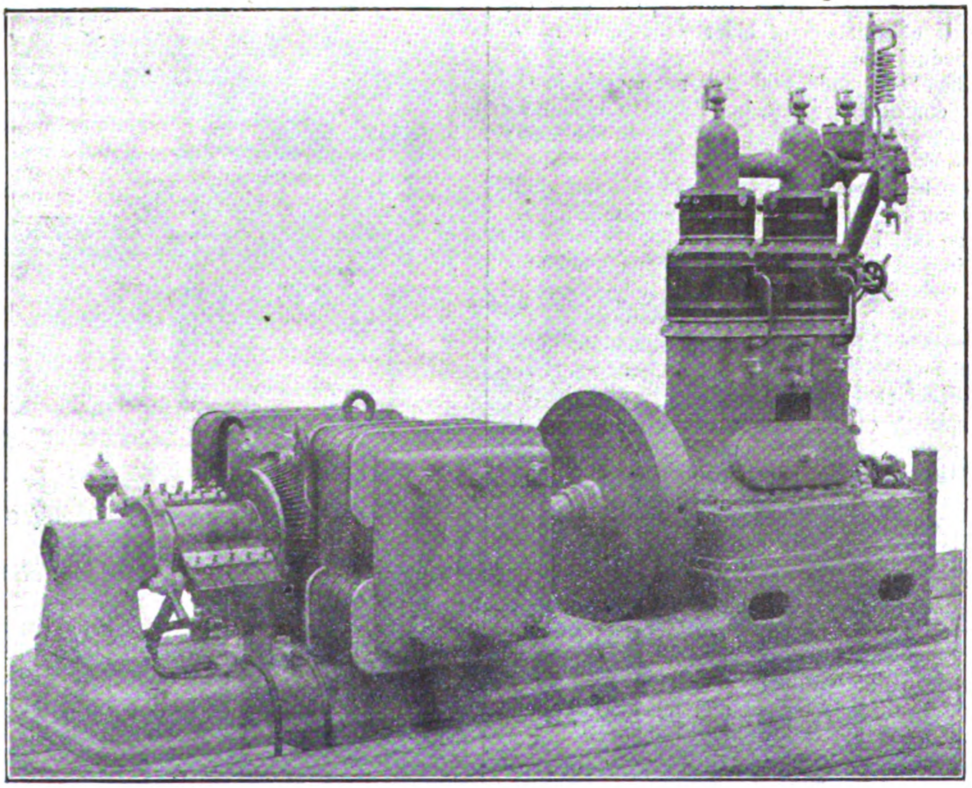

FIG. 3.—"Crewe" Steam-Dynamo Set.

the slow and laborious hand methods of getting out locomotive tubes. In fact, with the electric cutter, the furnace tubes of an entire locomotive can be detached in a little over half-an-hour, whereas it used to take from three-quarters to a whole day by the old methods. In several examples which we witnessed, it did not take more than 12sec. or 15sec. from the moment when the tool was in place to the moment when the cut was finished.

The "Webb" tube cutter is made in two or more patterns,

Digitized by Google

slightly varied according to the position of the cut on the tube. In Fig. 2 we give a set of scale drawings of the cutter for the smoke-box end of the boiler. The cutter for the fire-box end differs only in minor details. The position of the smoke-box cutter for both inside and outside cutting is shown. The cutter consists of a long spindle, at one end of which there is a 1½in. circular saw and at the other end an electric motor; while, in addition, there are switches for starting and stopping the saw, and an arrangement of cams whereby the saw can be made concentric or eccentric to the tube. The saw end of the cutter is poked into the tube, as shown in Fig. 2, the operator resting the motor end on his shoulder. While this is being done, the saw is set concentrically with the tube, fitting it quite loosely. When in position, the saw is set in rapid revolution, attaining a speed of about 3,000 revolutions per minute, and when running at full speed it is gradually thrown out of centre, the cutting teeth being thus pressed against the inside of the tube, and then revolved so as to make the saw centre describe a circle round the axis of the tube. This, of course, carries the cutting teeth round the tube on the inside, and the eccentricity being sufficient to push the teeth beyond the outside of the tube, a complete cut is made. To withdraw the cutter it is simply necessary to stop the saw, and to throw it into its concentric position, when the tool may easily be drawn out. One of these little machines had, we were informed, cut off as many as 10,000 furnace tubes without requiring any repair.

Portable electric drills are largely used, and it need hardly be said that a very large saving results as against hand labour. These tools are simple in construction, and need not be described in detail; but there is one form to be seen which perhaps may be referred to as being of more than ordinary interest. This is a drilling and rosebitting machine which is carried on a small truck to run on the narrow gauge railway which is seen everywhere in the works, or when necessary it can be wheeled on the shop floor. Centred in the body of the truck is an arm which can be moved radially through an arc of about 180deg., and on this arm is carried a drill spindle capable of being lowered or raised as desired. This tool is at present used for drilling and rosebitting holes in the frame plates of locomotives. The little truck is wheeled up to the frame to be operated on, and without further movement all holes within the range of the radial arm can be at once drilled or rosebitted as the case may be.

The electric power for the motors and lamps is derived from a number of dynamos scattered about the widely extended works, the machines in most, if not all cases, being driven by separate engines coupled direct. There is a large battery of E P.S. cells for steadying and forming a reserve of power for the lamp circuits. A special set of shops is set apart to the purpose of building the "Crewe" dynamos, which are used in these works, and elsewhere over the entire North-Western system. An interesting point in connection with these is the fact that all the parts are made to templet, so as to be interchangeable. The advantage of this plan on so gigantic a system as the London and North-Western Railway will be at once seen, and it will, no doubt, contribute to the reduction of the cost of the electrical plant on that railway system. The dynamos are, of course, made in various sizes and patterns, according to the class of work for which they are built. The armatures are, in general, drum wound; and the field winding is adapted to special requirements. Fig. 3 shows one of the "Crewe" dynamo sets for an incandescent lamp circuit. This particular machine is designed for an output of 550 amperes at 120 volts.

In the field of electric welding substantial work of an experimental nature is being done. A Thomson-Houston electric welding plant, capable of dealing with work in sizes up to 1¼in. wrought iron or steel bar, has been erected in a shop adjoining one of the smiths' shops. This plant is used both for welding and forging, and at the time we saw it it was being employed for forging rings and bosses on a number of wrought-iron rods.

We cannot leave the Crewe Works without noticing a feature in the incandescence lighting circuits which is not commonly met with. We refer to the "Webb and Thompson" ceiling rose, which is used in the goods stations and other places. The leads are tapped by means of two sharp-pointed screws which are screwed through the leads until they penetrate between the strands of copper. The two leads are clamped into the base of the rose without any preparation or removal of the insulation where the joint is to be made: and the contact of the pointed screws and the copper strands is a mechanical one, without solder. We understand that this simple form of ceiling rose is no less effective and safe that it is simple, and that it has been used with success for some time by the London and North-Western Railway Company. There are, perhaps, other places where it might be used. The rose is the invention of Mr. F. W. Webb and Mr. A. M. Thompson, of the North-Western Railway Company, to whom our best thanks are given for the kind assistance they have rendered us in our preparation of this account of electrical progress at Crewe Works.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, May 3rd.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting. The following Paper will be read: "Single-Phase Alternate-Current Motors," by A. C. Eborall.

MONDAY, May 6th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture, "Recent American Methods and Appliances Employed in the Metallurgy of Copper, Lead, Gold and Silver," by James Douglas.

ROYAL INSTITUTION.

5 p.m. Monthly Meeting.

SOCIETY OF ENGINEERS.

7:30 p.m. Ordinary Meeting at the Westminster Palace Hotel. A Paper will be read on: "Street Subways for large Towns," by Mr. Charles Mason.

TUESDAY, May 7th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "Alternating and Interrupted Electric Currents," by Prof. Forbes, F.R.S.

WEDNESDAY, May 8th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. The following Paper will be read: "The Extraction of the Rarer Metals from their Oxides," by Prof. Roberts-Austen, F.R.S.

THURSDAY, May 9th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "The Liquefaction of Gases," by Prof. Dewar, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Meeting at the Society of Arts, John-street, Adelphi. The following Paper will be read: "On the Recent Development of the Single-Acting High-Speed Engine for Central Station Work," by Mark H. Robinson.

IRON AND STEEL INSTITUTE.

10:30 a.m. Annual Meeting at the Society of Arts, John street, Adelphi.

FRIDAY, May 10th.

IRON AND STEEL INSTITUTE.

10:30 a.m. Annual Meeting at the Society of Arts, John-street, Adelphi.

PHYSICAL SOCIETY.

5 p.m. Meeting at Burlington House. The following Papers will be read: (1) "On the Iodine Voltameter," by E. F. Herroun; (2) "A New Method in Harmonic Analysis," by A. Sharp.

Electricity in Mines.—In the last batch of reports by Her Majesty's Inspectors of Mines, issued from the Home Office, Mr. Hall, the well-known inspector for the Liverpool district, on the question of lighting goes strongly in favour of electricity. Its use, he points out, is extending for illuminating pit banks and also the shaft sidings underground, though a portable and satisfactory miners' electric light is still wanting. An objection has been urged against an electric lamp on the ground that it would afford no test of the atmosphere of the mine; but this is scarcely shared by Mr. Hall, who declares that any drawback of that kind would be more than compensated for by the greater security of the lamp in other respects.

SPECIAL NOTICE.

Last week's number of "THE ELECTRICIAN" completed Vol. XXXIV. With this week's Number is issued (Gratis) the Index to that Volume. Complaints of non-receipt should be promptly made to the Publisher.

Owing to the growth of the electrical and allied industries the demands for space in "THE ELECTRICIAN" are, for the greater part of the year, so pressing that a permanent increase in the size of the journal has become necessary. To meet the increased cost involved by this step, and by other improvements, such as heavier paper and more numerous illustrations, the price of "THE ELECTRICIAN" will, from this issue, be advanced to 6d. Hitherto this sum has been charged when the number has contained a Supplement, and, as the industries grow, these may be more frequently necessary; but the practice of charging extra for Supplement numbers as issued will be discontinued.

The Subscription to "THE ELECTRICIAN," commencing with Vol. XXXV. (May 3, 1895), will be:—

	YEAR.	HALF-YEAR.	QUARTER.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

NOW READY.—Vol. XXXIV. of "THE ELECTRICIAN," bound in strong cloth. Price 12s. 6d., post free 13s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

THE BELT AND ROPE TRANSMISSION TRIALS OF THE SOCIÉTÉ INDUSTRIELLE.

Nearly twelve months ago, in the course of his remarks at the Institution of Electrical Engineers on Mr. CROMPTON'S Paper on "The Cost of Electrical Energy," Prof. KENNEDY announced that a series of what he hoped would be exhaustive and complete trials with regard to rope-driving was about to take place on the Continent. Reflecting that they often manage these things better abroad than we do at home, we awaited the results of these trials with no little nterest. But though thus heralded almost with a flourish of trumpets, the trials of the efficiency of belt and rope gearing, by the Commission appointed by the Société Industrielle du Nord de la France, have added little, if anything, to the stock of useful human knowledge on the subject. Ample machinery for an exhaustive inquiry was lent and assembled at the expense of numerous influential supporters of the Commission; a competent body of experimenters was gathered together; a splendid opportunity offered itself for the performance of genuine and useful research. Many questions pressed for solution; there was the great uncertainty as to the absolute efficiencies of ropes and belts,

Digitized by Google

when driven under the most favourable conditions; there were doubts even as to what are the most favourable conditions; there were matters to be settled as to the proportions and speed and driving pitch, or length of drive, which it is advantageous to adopt; there were countless other matters equally important. But, so far as we can gather from the published Report, a translation of which will be found in our columns, not one single item in this long list occupied the attention of the Commission. The mutual congratulation, vote of thanks to the boiler stoker, and proposal to request the Council of the Society to strike a medal commemorating the trials, stand in somewhat ludicrous contrast with the meagre programme of the actual research, and with the amount of time devoted to carrying it out. What is it that this Commission set itself to do, and what has it actually achieved with all its appliances? Engineers have long known something about belt and rope driving. They have known, for example, that these two forms of flexible gear must be arranged on different lines, as to the speed and distance at which they should be run, and the intensity of stress to which they should be subjected. Yet the Commission elected to run all the ropes and belts, of every kind whatever, on pulleys of precisely the same diameter, giving cotton belts, leather belts and manilla ropes exactly the same linear velocity! This alone is sufficient to detract from the value of any results which might have been arrived at. Moreover, the length of the drive in each case does not appear to have been measured; and the diameter of the dynamo pulley would seem to be too small for the ropes, and likely to punish them on the bend. In practice, also, the working stresses in belts and ropes are not so nearly equal as was the case in these trials.

With their plant equipped and arranged, the Commission proceeded to the settlement of two matters: (1) The amount of slip between the ropes or belt and the pulleys, and (2) the ratio of the indicated power developed in the steam engine to the electrical power developed at the terminals of the dynamo. The first of these is beside the point, and the second is vague and, under the circumstances, valueless. One cannot avoid the impression, on reading the Report, that the Commission attached considerable importance to this matter of slip; that they seemed to connect it in some way with the efficiency of the gear. Else, why did they devote so large a share of their attention to it? Yet, and especially under the ideally steady conditions of working maintained in these trials, slip signifies very little indeed, and it is no sort of indication whatever of the power wasted in the rope or belt. Under the irregular conditions of actual work the amount of slipping would be both absolutely and relatively different, when taking the various kinds of belts and ropes into comparison. But, perhaps, the most extraordinary feature of these trials was the vague and uninstructive way in which the wasted power was measured. If properly measured and analysed, this quantity should enable the absolute efficiency of the rope or belt to be determined, but an analysis from the figures supplied is quite impossible. The wasted power consists of power absorbed (1) in the engine, (2) in the rope or belt, and (3) in the dynamo. No attempt has been made to find the values of the first and the third quantities, and thus the second remains indeterminate. Yet it would have been a simple matter to measure the mechanical efficiencies of the dynamo and engine. Finally, there is an imposing display of indicator diagrams and engine dimensions, all to no useful purpose. An unequalled opportunity for the attainment of accurate knowledge on a point of high mechanical engineering interest has, it seems to us, been sadly wasted. Perhaps, after all, we may do this thing better at home.

REVIEW.

Elementary Lessons in Electricity and Magnetism. By S. P. Thompson, D.Sc., F.R.S., &c. New Edition. (London: Macmillan and Co. 1895.)

This well-known work has always been far more than a book for beginners, although it has served admirably for that purpose. The earlier issues contained a large quantity of matter of interest to the advanced student, and the practical applications of the subject were not neglected. The fact that seven years ago the circulation had already exceeded 40,000 copies, shows that the work was regarded as the favourite text-book among readers approaching the subject from the pure science side, and wishing to obtain a good grounding in both the pure and applied parts of the subject.

In the present edition, which has been largely rewritten and extended, the author has endeavoured to make his book comprehensive, and quite up to date, on both the theoretical and practical side; and he has certainly succeeded to an extent which will greatly increase the already high reputation of this book. The additions include a short account of Ewing's magnetic work; a description of the newer kinds of d'Arsonval galvanometers and electrostatic voltmeters; a *résumé* of Lodge's lightning rod work; the theory of the magnetic circuit, and the idea of magnetomotive force; a description of the current balances of Lord Kelvin, wattmeters, supply meters, arc lamps and their classification, glow lamps and their mode of grouping, inductance and its measurement, alternate currents, alternators, transformers, alternate-current motors, and polyphase transmission of power. The portion dealing with direct-current dynamos is fuller than in previous editions, and some of the fundamental calculations made in the design of these machines are discussed in connection with the subject of the magnetic circuit. The last chapter contains an excellent description of the properties of electric waves, and of the more important experiments which have been made with them. There are several appendices, including some useful tables, the official specifications of the various electrical units, a large number of problems and exercises, and, lastly, an alphabetical index for purposes of reference. The book is very fully illustrated, and, as is characteristic of all Dr. Thompson's work, the style of writing is both clear and interesting.

We have merely given the barest outline of the nature of the changes introduced into the present edition. These can, perhaps, be best described by saying that the author has succeeded in his principal object, stated in a paragraph of the preface, where, after alluding to the great extension of electrical science in recent years, the writer states that "this expansion of the science, and of its practical applications, has rendered more difficult than before the task of presenting with sufficient clearness, yet with necessary brevity, an elementary exposition of the leading phenomena, and of their relations to one another."

The chief criticism we are inclined to offer is that we doubt the wisdom of attempting in a book, which is styled elementary, so complete an exposition of the subject. It is impossible, however well the book may be written, to properly discuss, in the space at the disposal of the author, such a great number of electrical matters. As a consequence some of them have to be referred to very briefly, as, for instance, in Chapter VI., where five small pages are all that are devoted to describing five methods of determining electromotive force, five methods of determining the internal resistance of cells, and six methods of determining capacity. Such a brief catalogue seems merely to supply a number of reasons for seeking information elsewhere. It is also a pity that the immediate wants of the beginner have not been more considered. In spite of the advanced character of much of the contents of this edition, there still remains a considerable fraction of the book written in a style, and dealing with subjects, admirably suited to the mere beginner; and, if the paragraphs in which these parts occur had been marked by means of an asterisk, or in some other suitable manner, the value of the book would have been much increased. It is true that the

Digitized by Google

author is already engaged in writing a book "for beginners" on the same subject, and "adapted to the elementary stage of the South Kensington syllabus." There is no doubt that this book, when written with the free interpretation which the author will rightly give to the above description of its scope, will admirably supply the wants of the beginner. Nevertheless, at present the very success of the author has deprived the elementary reader of a book suitable for his wants, by supplying him with one styled elementary, but really advanced. The matter which such a student requires, although all contained in the present volume, is so mixed with other matter which is beyond his powers to understand, that he will probably be driven to resort to books of a much inferior stamp.

The first chapter is admirably written for students who already have a slight knowledge of the subject, but for a beginner parts of it are likely to prove most difficult. It deals with electrostatics, though for this subject the author adopts the grandmotherly title of frictional electricity. His liking for old fashions, however, ends at the title, for he presents the subject in the most modern way, introducing the ideas of lines of force and tubes of displacement in order to explain the phenomena of electric attractions and the action of the electrophorus and influence machine. Prof. J. J. Thomson has largely developed these ideas in his recently published supplementary volume; and the author of the present work, so long ago as the year 1888, used them with considerable success, to throw a new light upon the mode of action of the Wimshurst machine, in a valuable Paper which he read before the Institution of Electrical Engineers at that time. Admirable, however, as these lines of force may be in connection with the latest developments of electrical theories, it may well be doubted whether it is wise to bring them to the notice of a student wishing to obtain "elementary lessons in electricity and magnetism." In any case, if it was thought desirable to describe the phenomena of electrostatics in terms of lines of force, it would have been much preferable to commence the book with a chapter on magnetism, a subject in which numerous experiments of a simple character can be devised to convince the student of the physical reality of similar lines of force, and the general properties which they possess. In electrostatics the experimental means of exhibiting these lines are quite insufficient to give the student an intelligible idea of them; and the explanations of the phenomena in terms of them, although of great interest to the advanced student, are not so simple as those in terms of positive and negative charges.

When dealing with the subject of permeability, the properties of the hysteresis curve are briefly described in a couple of well-written paragraphs. We believe that this is the first time that these properties have been described in a text-book not written expressly for technical readers. No mention is made of it in the former edition of this work, nor anywhere else that we know of, with the exception of technical books or the Proceedings of scientific societies. This is the more remarkable when the theoretical importance of these phenomena is considered, and can only be accounted for by the comparatively recent date of the discoveries themselves.

In our opinion it is to be regretted that the author has introduced into his book calculations based upon the law of the magnetic circuit. The imperfect analogy between the electric and magnetic circuits is useful to anyone having already a good knowledge of the former, and has proved of great service to many engaged in the practical applications of electricity, since it has helped to simplify the conception of the magnetic circuit. But it is a mistake in a book dealing with the subject more from a scientific than a technical point of view, and intended for ordinary students, to compare an exact law, like that of Ohm, in which the ratio of force to flux is a constant, with an approximate law, like that of the magnetic circuit, in which the ratio of force to flux is a variable, determinable merely by experiment, and in which a number of leakage constants (or rather variables) have to be dragged in to completely account for the facts. We should be the last to deny the important services the so-called law of the magnetic circuit has rendered in simplifying the calculations necessary to predict the action of the various types of electromagnets used in the practical applications of electricity. At the same time, a scientific student would be justified in objecting to paying much reverence to a law which only seems to predict experimental results, after these same experiments have been made for the purpose of finding a number of so-called constants necessarily determined in this way before the law can be applied at all.

NOTES ON SUBMARINE CABLE WORK.

BY H. D. WILKINSON.

(*Continued from page 450, Vol. XXX.*)

The Localisation of Faults.

31. **Preliminary.**—In the former articles we have examined the machinery used and practice followed on board a cable steamer while carrying out a repair. We now propose to review some of the electrical tests for the localisation of faults and breaks, adhering to the practice and methods in common use to-day. Ships go out now to repair faults of a minuteness scarcely ever met with ten years ago, on account of their more rapid development at that time.

The covering of brass tape, by which the core of all modern cables is protected from the attacks of the submarine teredo, is a means of preventing the previously rapid development of a fault under the action of the current, because the gas evolved has no free escape, and becomes occluded on the surface of the tape. The result of this condition is that faults are of much higher resistance, although they occur in less numbers, except as regards fractures, and it may be said that finality has not been reached in the tests used to locate these small and difficult faults. Further, as regards duplicate cables, a fault, or even a total interruption of one cable, does not trouble the public, whose messages still go through by the other; but it is a matter requiring prompt action on the part of the owners, in order to keep the duplication intact; and, consequently, faults are dealt with as soon as they occur, and are oftener than ever of a very minute character. Such faults require very rapid observations on the instruments on account of their polarisation, and this action is so instantaneous in some cases as to render the results from one end quite unreliable; but, notwithstanding these difficulties, the smartness with which repairs are carried out to-day is proof that considerable practical advances have been made.

In these papers some acquaintance must necessarily be assumed with electrical apparatus. The Wheatstone bridge, galvanometer, keys, batteries, and commutators are nowadays within reach of all who have entered on any branch of electrical work, and the practical use of them is very soon acquired.

Faults are sometimes so small as not to have the slightest effect on the signals through a cable, and, indeed, would not be noticed at all if it were not for periodical tests. Other kinds of faults make their presence felt on the signals at once, and at times there are total breaks or dead-earth faults, which immediately put a stop to communication. But, however small a fault is when first detected, it will gradually open up under the action of signalling currents, even should the original cause have ceased, and on this account it is usual to proceed at once to remove such. Before the ship leaves, the nearest possible approximation of the position of a fault is made by tests from both ends, and after she arrives at the estimated position and cuts in on the cable, similar tests are made between the end on board and the shore to obtain a nearer result.

It will be seen that these tests are of great importance, as, when carried out skilfully, the ship's time at sea is lessened, and the business of the company quickly restored to its accustomed channel.

32. **The Earth Overlap Test.**—In cases where the fault makes only partial earth—that is, when it offers anything above, say, 20 to 30 ohms resistance—the observers at either end can speak to each other, arranging times for testing, and

Digitized by Google

then compare results. A reliable test, depending on results from both ends, is that first published by Messrs. A. E. Kennelly and James Anderson in *The Electrician* of July 17, 1885 (Vol. XV., p. 177), and which has since been used with success in difficult cases. The principle of the test is to take readings on the bridge in turn at either end of the cable, the opposite end being earthed for the time, and, by adding a resistance to the end of the cable nearest the fault, to make both bridge readings equal. Whatever bridge ratios are used at one end should be used at the other, and the batteries should have approximately the same E.M.F. and resistance; the current through the fault will then be the same, and its resistance constant for the tests from both ends. The connections for testing at one end are given in Fig. 102. A plug is put in 1 (of the commutator) to connect cable to bridge for testing, and is taken out of 1 and put in 2 for earthing the cable while the other end tests.

The tests may be taken with one current only to false zero, or by reversals of current to instrument zero. If with one current the zinc current should be used by both ends, as by this the current in both tests flows through the fault in the same direction, and in such a direction as to open it up (although it flows through the cable in opposite directions). The time for earthing and testing being agreed upon, the first pair of tests is taken and compared. The end nearest the fault will test lower than the other. Now add a resistance to the lower end equal to the difference between the two results. On trying a second pair the readings will be more nearly alike than before, but may still not be equal. The added resistance is then increased by the difference of the two readings if the same end still tests the lower, or is reduced by a like amount if it tests

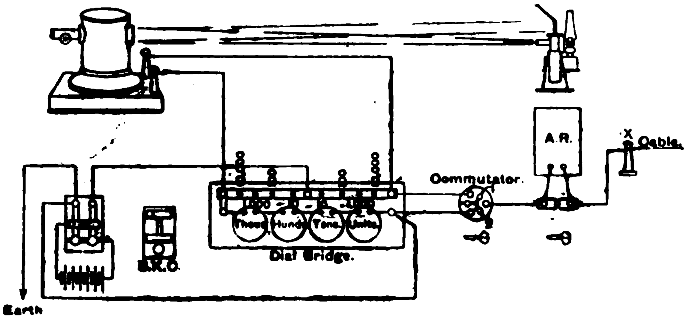

FIG. 102.

too high. More pairs are taken in this way till both ends test the same. The difference between the results at both ends when testing to earth is always less than the true amount by which the added resistance should be increased or diminished to produce equality between the readings.

Mr. Kennelly, in a communication to the Institution of Electrical Engineers (*Proceedings*, Vol. XVI., page 581), has given a formula (derived by differentiating the difference between the earth readings with respect to the added resistance), by which the approximate value of the added resistance may be determined after a pair of earth readings have been taken with a given added resistance. This is given below in a simple form.

Free the end nearest fault and test from the other, giving a balance, say, of A ohms, and let P be the sum of the line perfect and added resistance. Then the latter must be increased or reduced by the difference between the two earth readings multiplied by the following fraction :—

$$\frac{A^2}{P\left(A - \frac{P}{4}\right)}.$$

This fraction is more easily worked out when written

$$\frac{A}{P} \times \frac{A}{A - \frac{P}{4}}.$$

Another way is to take a pair of frees and increase or diminish the added resistance by the difference between the readings.

When earth readings are the same at both ends, free readings should be also equal, with the same added resistance. The free overlap is, however, not so reliable as the earth overlap, as it is more affected by low places beyond the fault. When freeing the cable it should be disconnected at the terminal X (Fig. 102). The added resistance simply makes the cable longer in order to place the fault electrically in the centre of the line. The formula is therefore the same with either earth or free overlap. Calling R the correct added resistance (proved by equal results from both ends), L the line perfect, and x the distance in ohms from end nearest the fault (Fig 103), we have

$$R + x = L - x;$$

whence $$x = \frac{L - R}{2} \text{ ohms.}$$

In the manipulation of this test it is best that the end which tests last in one pair should test first in the next. The

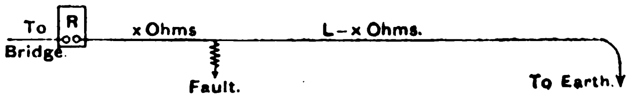

FIG. 103.

time taken in testing at each end can then be kept more nearly the same, and the fault is given less chance to alter. If this is not done, the fault may polarise and make the result too high, even with the right added resistance.

33. **Earth Overlap as a Loop.**—When testing cable in tank, or a faulty cable looped to a duplicate cable, the earth overlap may be used as a check on the ordinary loop.

The cable ends are first connected as usual to the line and earth terminals of bridge, and a reading taken. Then the cable ends are reversed, and the bridge balanced again. The end to line of bridge when the lower of these two readings is obtained is that nearest the fault, and to this end is added a resistance equal to the difference between the two readings. The ends A and B

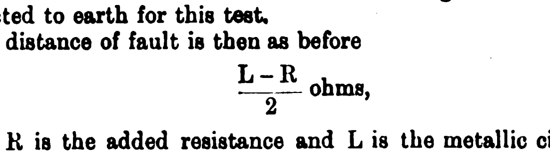

FIG. 104.

(Fig. 104) are reversed on the bridge for each reading, readjusting the added resistance after each pair until the readings are the same with either end of cable to line of bridge and the other to earth. The earth terminals of bridge and key are connected to earth for this test.

The distance of fault is then as before

$$\frac{L - R}{2} \text{ ohms,}$$

where R is the added resistance and L is the metallic circuit measured with the ends of cable to line and earth of bridge, and the earth wire taken off key. As a loop, excellent practice can be gained in using the overlap. The battery power and bridge are identically the same for each reading. Moreover, the correctness of the added resistance checks itself in one observer's hands, and the effect of differences in the time taken over each reading can be readily seen.

(To be continued.)

Telephonic Communication between Ships and the Shore.—An experiment in connection with telephonic communication between the watch ship "Heimdal" and the land was recently made in the harbour of Kiel. At the forthcoming opening of the Baltic ship canal, it is proposed that all the war vessels—German and foreign—which take part in the opening ceremonies, shall be enabled to communicate with the shore, telephone cables being attached to all the harbour buoys.

LEICESTER ELECTRIC LIGHT AND POWER STATION.

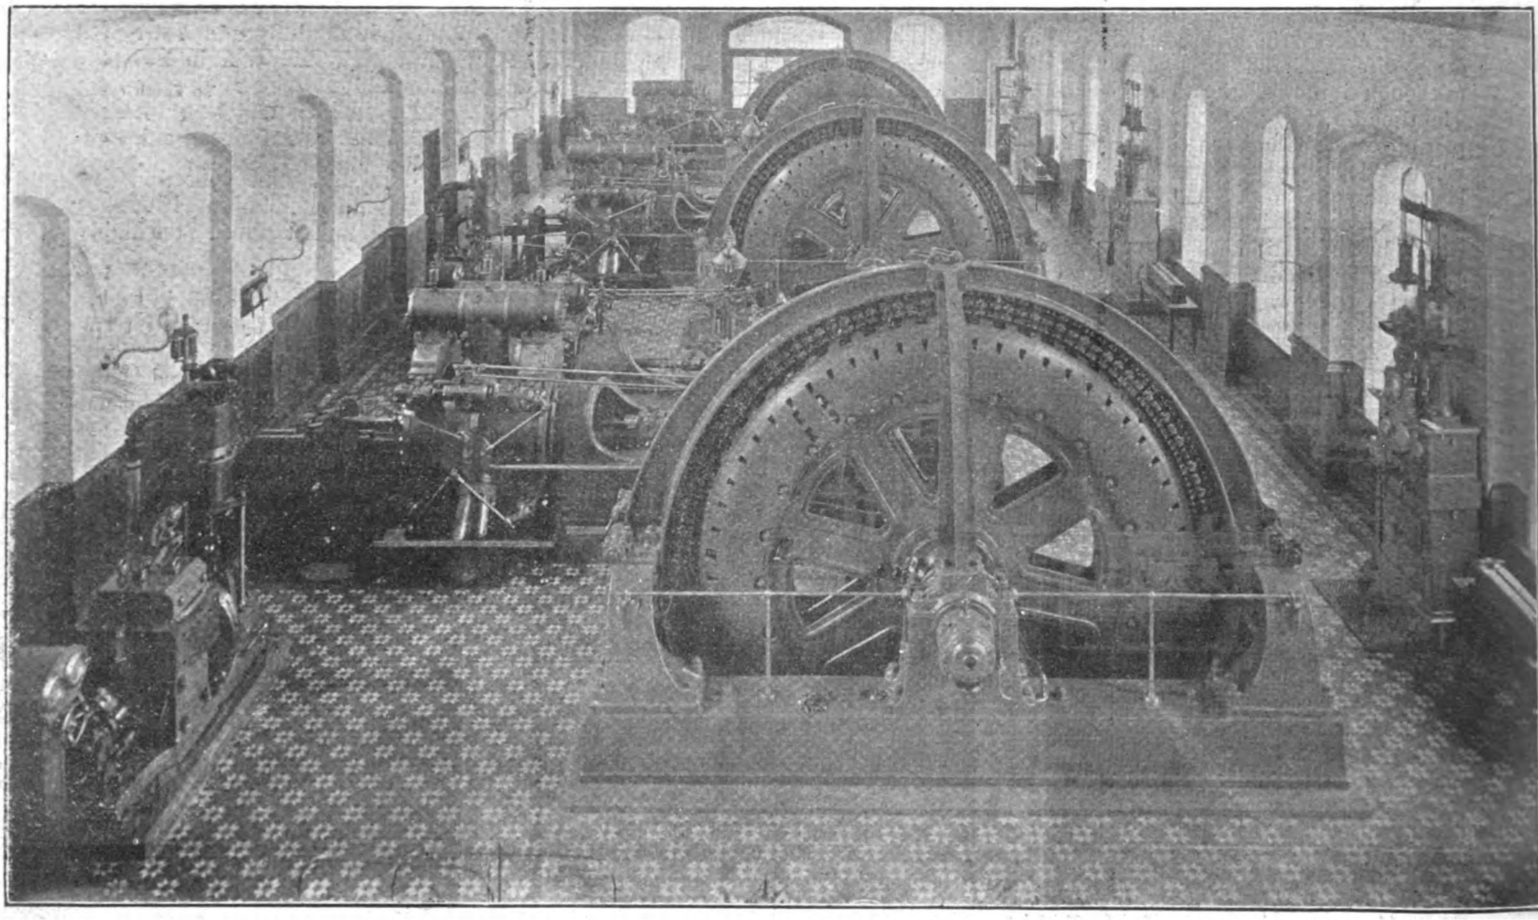
Unusual interest has perhaps been taken in the Leicester electric lighting scheme because the Corporation have carried out the work without engaging the services of an expert in the usual way, and also because it has been understood that both of the contractors for the plant—steam and electric—have made special efforts to supply the best possible machines they were capable of, and the buildings, for which Mr. Alfred Colson, the borough engineer, is responsible, probably contain, as will be seen from our illustration, the handsomest engine room of all the central stations of Great Britain.

The system is a high-pressure alternate-current one, with street sub-station transformers and a low-pressure distribution, the pressure of the feeders being 2,000 volts, and that of the low-pressure network 100 volts. In many respects the station equipment follows continental practice rather than that hitherto the custom in England. The plant is divided into three large units each of 200 kilowatts, with a smaller unit of 75 kilowatts for the light load. Compound condensing engines are coupled direct to the alternators through flexible couplings, and the revolving field-magnets act as flywheels. The steam pipe and electric conductors are all carried in a basement under the flooring formed by spaces left between the foundations of the machines and the main walls.

The flooring is formed of rolled steel joists, filled in with cement concrete, and paved with tessellated tiles. A dado of stained and varnished match boarding, with moulded cap and skirting, encircles the room. The room is lighted by double tiers of windows on both sides, except where the boiler house abuts, and one end is left plain for extensions. The roof is supported by wrought-iron principals, and is formed of pitch pine rafters and purlins filled in with diagonal match-board panels, stained and varnished. A 15-ton electric overhead traveller spans the entire width, and can be traversed from end to end of the room. The walls are faced with cement, and whitened. The general effect is extremely fine, and Mr. Colson is to congratulated on the design, by which he has realised an artistic and commodious station, with facilities for getting at any part of the plant.

The most striking features of the plant are, perhaps, the engines and the switching and regulating devices, but there are interesting details and improvements of various kinds in every part. Commencing with the boilers, there are at present four Babcock and Wilcox water-tube boilers, each of 250 actual horse-power, arranged in two batteries, with foundations for extensions amounting to 50 per cent., under the same roof. The working pressure is 120lb. per square inch, and the firing is done by hand. Gas coke from the gasworks is the cheapest fuel available, and is used at present. The feed water for the boilers is supplied from a tank, holding about 600 gallons. The exhaust steam from the exciter and pumping engines is taken into this tank and raises its temperature before it is delivered through the economisers to the boilers. The fuel economisers are also by Babcock and Wilcox and embody all the latest improvements. There are two vertical Brush three-throw pumps, direct coupled to Brush vertical steam engines. Each set is equal to the full load demand of the present plant, and the feed can be regulated to a nicety by levers which shut off the suction to each of the three rams as required. All the water and steam pipes are in duplicate, and valves are arranged so as to isolate any part. The feed water-pipes are of 3in. galvanised iron. The main steam pipe is of 6in. wrought iron, arranged in a ring with straight-through valves of the parallel slide type, and Giepel's patent steam traps. Magnesia sectional covering is used as lagging. The exhaust pipe from the condensers is of cast iron, 12in. in diameter at its largest section.

The engines, by Messrs. Hicks, Hargreaves and Co., of Bolton, are horizontal compound condensing, with Corliss gear of special design. The three large ones indicate 350 H.P. each, and have governors unusually large and powerful, which control the gear on both cylinders. The cylinders are respec-



Engine and Dynamo Room of the Leicester Municipal Central Station.

Digitized by Google

tively of 16in. and 30in. bore with 30in. stroke. The speed is 96 revolutions per minute. Each engine has a jet condenser with circulating and air pump worked off a rocking lever on the tail rod of the low-pressure piston rod. The smaller engine is of similar design, except that Corliss gear is not fitted to the low pressure cylinder, and only the high-pressure gear is governed. The condensing water is got from the River Soar, and is discharged into a canal alongside the station. The three 200-kilowatt alternators are of the Mordey-Victoria type, and are similar in general design to those in use at the Bankside station of the City of London Electric Lighting Company. They have 120 coils in the armature, each wound on slate formers and fixed in German silver and ebonite brackets. They are set radially round a gun-metal ring bolted to a cast iron frame, which is divided into four sections, two being below the floor level. Each section is centred on end girders of cast iron, and can be readily swung back for inspection and repair of the coils. As the two halves of the armatures are connected in parallel, an equaliser is placed in one of the end girders. The field-magnets are of massive steel castings, with 60 pairs of polar projections, the over-all diameter being 12·5ft. The excitation is provided by a single central coil having two gun-metal collecting rings mounted on the shaft, which runs in large swivel bush bearings. The lubrication is effected by a continuous circulation of oil maintained by a pump worked off the shaft. The smaller alternator gives 75 kilowatts at 118 revolutions, and is similar in design to the large ones. The pressure is 2,000 volts, and the frequency 100 ∿. The exciting plant consists of two Brush-Falcon compound wound steam dynamos, each having an output of 12 kilowatts, either being capable of exciting all the alternators at the same time. Raworth's patent electric governors are fitted to these engines, and by means of a resistance in circuit the whole of the station can be regulated from one place.

As previously mentioned, one of the most interesting features of the station is the switching arrangement. There is no main switchboard, its place being supplied by a number of so-called switch pillars, which form the features of the Raworth interlocking system. Each alternator has a switch pillar containing a system of interlocked switches, which prevent the closing of the main circuit before the field circuit and synchronising circuit are closed, and also the opening of the field circuit before the main circuit is open. A synchroniser is provided for each of these pillars, and is in mechanical connection with the main switch. Conductors are taken from the four "alternator pillars" to a "dividing table," and from thence through separate switches to two "circuit pillars" containing double-pole switches, fuses, and ammeters for each of the two concentric feeders, which are laid into the limited area. Each exciter has an automatic switch pillar acting on a zero cut-out, and preventing the return of current on the exciter in case of accident to engine or dynamo, and also closing the exciter circuit when, and not until, the exciter has attained the proper pressure. There is also an "omnibus pillar" for dealing with the exciters, travelling crane motors and other circuits in the station. The travelling crane will safely lift 15 tons, and is operated by hand or by three electric motors, each controlling one of the three motions through worm gearing with rolling bearings. The switches are of the interlocked type, and are fixed in a cage below the crane.

The cables are all of the Fowler-Waring concentric make, being lead-sheathed and armoured with steel tape, excepting in the case of the high-pressure ring main in the limited area where, as the cables have been laid in 3in. iron pipes, no armouring is used. The outers of the system are earthed at the station through a switch at each of the "circuit pillars," so that each feeder may be disconnected from earth for testing. The two feeders running to No. 1 sub-station in Market street are each about 1·5 miles in length, and are 0·146 sq. in. in section. From No. 1 station the high-pressure mains are run round the limited area in a ring main 0·097 sq. in. in section, the cable, which is braided over the lead sheathing, being run in 3in. C.I. pipes. There are eight transformer stations in the ring, each with suitable switching devices, so that any section can be disconnected for testing or repairs.

The transformer stations have an internal measurement of 7ft. 6in. long, 5ft. 6in. wide, and 7ft. high, the sides and ends being segmental and rising 6in. The walls of the chambers are formed of good hard bricks in cement in two thicknesses with an inch space between. This is filled up with asphalte, which is continued under the floor and roof, thus making the whole perfectly water and gas tight. The roof is formed of rolled steel joists filled in between with cement concrete. The manholes have double doors, and iron steps are built into the inner skin of the walls. Ventilation is secured by an air inlet and outlet. The bell mouths of the tubes carrying both the high-pressure and low-pressure cables are caulked with vulcan cement, and a half-inch hole about a foot back from the wall of the chamber communicates with a ventilating flue. This arrangement allows of the escape of any gas which may find its way into the pipes. The transformers are of the Mordey-Victoria type, each being provided with a double-pole H.T. trigger switch in a C.I. lock-up box. The "secondaries" of the transformers are connected through double-pole switch fuses to omnibus bars in connection with the low-pressure network. All the transformers, switches, joint boxes and frames are earthed. The low-pressure mains have a sectional area of 0·146 square inches, and are laid direct in the ground. House connections are made by means of concentric armoured cables jointed with wiped joints protected by a T-shaped casting. The house service switch used is of a new form recently designed by the Brush Company. It includes a double-pole switch and fuse specially arranged for connecting a concentric cable service to separate house mains.

The plant has been at work since December 19th last, lamps equal to 6,000 8 c.p. being already connected. The price charged is 6d. per unit. The Corporation have organised an electric light fittings department, and have succeeded in securing the greater portion of the wiring and fitting that has been carried out in the town. The profit from this is to go towards reducing the cost of supplying electricity. No cables have yet been laid beyond the limited area, but the residential district, Stoneygate, will shortly be served. The authorised expenditure is £42,574, and of this about £33,000 has been spent up to date. The capacity of the present station plant is roughly 18,000 8 c.p., so that not more than one-third of the plant is yet utilised.

Mr. Alderman Lennard, the able and energetic chairman of the Gas Committee, to whom so much of the credit of the scheme is due, says he hopes to reduce the price to 4d. per unit as soon as the full output of the present plant is in demand. Until the Board of Trade returns for the first year's running expenses are made up, it will not be possible to form an exact opinion of the financial advantages of this scheme; but if the experience of the past three months be maintained, it would appear that the figures will come out all right. Also it would be out of place here to question the suitability of the plant, and still more so to emphasise the unfortunate experience which some of the Brush alternators have met with in London, Sheffield, and elsewhere. The Brush Company's officials are fully alive to the causes which led to their troubles and have apparently overcome them, since at Leicester the alternators and feeders are so arranged that parallel running is the normal condition, except during light load.

BELT AND ROPE TRANSMISSION TRIALS.

It was at the meetings of May 25 and June 25, 1893, in the course of an account of an investigation into belt and rope transmission (an investigation undertaken and published by M. V. Dubreuil) that the idea of making a series of comparative tests of the power absorbed by these two systems of transmission occurred to the Civil Engineering Section of the Société Industrielle du Nord de la France. M. Dubreuil, with a view to obtaining facts upon which to base his investigation, had asked the opinions of a large number of French and foreign constructors. Their answers were somewhat vague and contradictory, and they aroused amongst all a wish to have the

Digitized by Google

matter exhaustively investigated. Thereupon M. A. Dujardin, an engine maker of Lille, who was present at these meetings, offered to supply at his own expense, for the purpose of a series of practical experiments, a 200-H.P. steam engine, to be fitted as required either with a rope or belt pulley of 4½ metres diameter. This offer was accepted, a Committee of five nominated, the number being increased to nine later on, and this Committee was authorised to apply to individuals, who although not belonging to the Société Industrielle, might be interested in the matter. This appeal was very successful, and on November 5, 1893, six gentlemen, chosen by outside adherents in general assembly, were elected by that assembly and added to the Committee appointed by the Civil Engineering Section. The committee from that time was composed of the following 15 gentlemen: M. Bonet, chief engineer of the Association of Steam Owners of the North of France; Prof. D. S. Capper, of King's College, London, and delegate of the Institution of Mechanical Engineers; M. Chapuy, mining engineer of Lille; M. de Cuyper, manager of the Van den Kerkove Works at Ghent; M. V. Dubreuil, engineer and architect of Roubaix, delegate from the Society of Civil Engineers of France, and of the Old Students' Association of the National School of Arts and Industry, president of the Civil Engineering Committee and of the Ropes and Belts Tests Committee; M. A. Dujardin, Engineer of Lille; M. Goerich, engineer, manager of the Société Alsacienne de Constructions Mécaniques of Mulhouse and Belfort; M. Gruson, chief engineer in the Ponts et Chaussées, and director of the Industrial Institute of Lille; Col. Laussedat, director of the Conservatoire des Arts et Metiers of Paris; M. Olry, mining engineer, delegate appointed by the Managing Committee of the Association of Steam Engine Owners of the North of France; M. Neu, electrical engineer, old student of the Ecole Polytechnique, Professor at the Industrial Institute of Lille and co-delegate of the Society of Civil Engineers of France; M. Schmidt, chief engineer to the Association of Steam Engine Owners of the Somme; M. Vigneron, manufacturing engineer and manager of the cotton mills of MM. Wallaert Frères, of Lille; M. Villain, engineer, of Lille; M. Witz, manufacturing engineer and science professor at Lille.

On February 5, 1894, the Committee met and adopted the following resolutions:—(1) The steam engine is to have a double flywheel or two flywheels, one for belts and the other for ropes; (2) the dynamo is to be direct-driven,* and provided with two pulleys, one for belts and one for ropes; (3) the dynamo is to be placed on a sliding bedplate to enable the tension of the ropes to be regulated at will; (4) the cotton belt is to be obtained from M. Lechat, of Ghent and Lille; the homogeneous belt from M. Domange, of Paris; the leather belt from M. Lemaire, of Tourcoing; the ropes from MM. Saint Frères, of Paris. The experiments are to be conducted by making on each occasion several alternative tests with ropes and belts. The tests being comparative, and the double flywheel enabling the Committee to work alternately with ropes and belts, it may be assumed that during the course of an experiment the mechanical efficiency will not vary, and secondly, there will be no necessity to ascertain what it amounts to.

Such, broadly, was the programme which the President of the Committee was to carry out, and to ensure success M. Dubreuil obtained the support of competent experimenters chosen from amongst the members of the Committee who were good enough to undertake the task, and of all these gentlemen who were good enough to consent to present various apparatus at the least cost in order to reduce as much as possible the expense of an installation which might have required an expenditure of 150,000fr. In the first category of supporters came M. Bonet, Profs. Neu and Paillot and MM. Loriol, Finet and Maréchal (electrical engineers) and M. Dujardin, who between them formed a staff of practical men whose competence is beyond dispute. In the second category came the Société Alsacienne, who laid down and superintended the working of a 200-H.P. dynamo, especially constructed for these trials, MM. Gabriel et Anguenault, of Paris, who supplied 1,800 incandescent lamps, M. Henneton, of Lille, who supplied 300 additional lamps; the Société Industrielle des Téléphones, who supplied the electric wiring; MM. Lazare Weiller et Cie., who furnished the heavy copper conductors; M. Sage et Grillet, who supplied the lamp-holders and accessories; M. Loriol et Finet, who superintended the general arrangement of the electric installation; and MM. Lechat, Lemaire, Domange and Saint Frères, who furnished the belts and ropes. These firms gave their services absolutely free. In addition should be mentioned the Compagnie du Chemin de Fer du Nord, who lent one of their large boilers, and MM. Dujardin et Cie., who supplied, not only the engine, the steam, and the site, but also discharged the incidental expenses of the installation. All this unhoped for support ensured the success of the experiments decided upon.

Carrying Out of the Tests.

In carrying out the experiments, the following principle was assumed as an axiom. Having given a constant resistance, and the power intended to overcome this resistance, all variation of power must be debited to the means of transmission, belt or ropes, which alone were capable of altering the *régime*. Such was the axiom assumed by the Committee, and such was the axiom practically made use of. The resistance was composed of incandescent lamps demanding a constant number of watts. The revolutions of the engine and the dynamo were counted, the dynamo being kept at a constant speed in all the trials, and indicator diagrams were taken when the load was steady.

Methods Taken to Maintain the Constancy of the Load.

One of the most important points was to maintain the load constant. This object was obtained in the following manner. Observations were taken throughout the trials to make sure that the difference of potential at the terminals of the bank of lamps, and that the current passing through the lamps was constant; in other words, that the number of watts absorbed by the lamps was the same in all cases. Measurements of difference of potential and current were made in M. Dujardin's office at a sufficient distance from the lamps and dynamos to annul any disturbing influences. The apparatus was lent by the physical laboratories of the Science Faculty and Industrial Institute of Lille.

To measure the difference of potential a Siemens and Halske torsion voltmeter was made use of. This voltmeter, which was carefully standardised, enabled one to read with great ease to ⅓rd and even to ¼th of a volt. The measurement of the current would have presented some difficulty, but as it was not necessary to know its exact value, but only to make sure that it remained constant, the operation was carried out in the following manner:—At two points about one metre apart on the main circuit two fine wires led to the terminals of a sensitive Wiedemann-d'Arsonval galvanometer. Readings were taken by Poggendorf's reflection method, and the sensitiveness of the method was such that it was found necessary to diminish the sensitiveness of the galvanometer in order to keep the spot on the scale. A switch enabled the direction of the current to be reversed, and consequently the direction of the deflection on the scale, enabling the correction of possible variations of zero due to the disturbance caused by the masses of iron in the neighbourhood of the apparatus. The difference between the two readings remained constant if the current itself remained constant.

It should be added that the trial measurements were not commenced until after everything had been in operation a certain time, that is to say, until the temperature of the wires had become as constant as possible.

Every ten minutes the constancy of the volts and amperes was verified. If the difference of potential was found to have varied, it was brought back to its normal value by adjusting the engine governor and altering the speed, the correction being completed by a regulation of the field. As soon as the volts were brought to their proper value and if a variation of the current was observed, this latter variation was corrected by switching lamps in and out on the bank, then indicator diagrams were taken.

Date of the Trials.

It was in the course of August 7, 8, 9, 1894, that the trials were carried out. Not only did the members of the Committee

* "Direct-driven" here implies, not direct-coupled, but the absence of countershaft or intermediate gear.—[ED. E.]

Digitized by Google

take part in them, but also anyone who expressed a wish to do so. An August 9th the Committee met and drew up the following minutes, which prove the perfect regularity and success of the trials.

Trial of August 8th.

The morning of August 7th was occupied in carrying out the preliminary runs intended to initiate the assistants into their various duties, in order to ensure the subsequent complete regularity of the operations. The apparatus being new, the results might possibly have been vitiated if the actual trials had been commenced from the start. In the course of these preliminary runs it was observed that the electrical measuring instruments, which were placed in the erecting shop, were influenced by the movement in their vicinity of the masses of iron, and they were taken, therefore, into the office of M. Dujardin.

The work of carrying out the trials was allotted as follows:— (1) Boiler: This was looked after by a stoker belonging to the Compagnie du Chemin de Fer du Nord, who had instructions to keep the pressure constant at 6·75 kilogrammes (96lb. per square inch). (2) Steam engine: The taking of indicator diagrams and general superintendence was entrusted to the engineers of the Association of Steam Owners, who were under the direction of M. Bonet. (3) Dynamo: This was looked after by MM. Loriol, Finet and Maréchal of the Société Alsacienne. (4) Speed Counters on Engine and Dynamo: This duty was entrusted to the engineers belonging to the Association and of M. Dujardin's firm. (5) Lamps: These were looked after by the Société Alsacienne. (6) Electrical Measuring Instruments: The readings were taken by Profs. Neu and Paillot.

The general direction of the experiments was undertaken by M. Dubreuil, President of the Committee.

In order to ensure uniform trials the following programme was adopted for each run: (1) The plant was first run light for 30min.; (2) preliminary run, loaded, lasting 30min.; (3) then 10min. for regulation; (4) test, with 15 indicator diagrams, taken for 10min., trial lasting altogether for 140min.; (5) diagrams taken running light; (6) removal and weighing of the transmission gear.

In the evening of August 7th a test was made with ropes. No notice was taken of the first test, in which the voltage rose to 104, a further test at 94 volts being made. The trial commenced at 3:40 and ended at 6 o'clock. In the course of this trial the experimenters noticed that one of the speed counters had got out of order. During this first preliminary trial Profs. Neu and Paillot reported an absolutely steady voltage.

Trial of August 8th.

In the morning the cotton belt supplied by M. Lechat was tested. A start was made at 7:50, and the load was put on at 8:20. The actual trial lasted from 9:10 till 11:30. In the afternoon the leather belt supplied by M. Lemaire was tested. A start was made at 3:10, the load was put on at 3:40. The trial lasted from 4:30 till 6:50.

Trial of August 9th.

In the morning the leather belt supplied by M. Domange was tested. A start was made at 7:50, and the load was put on at 8:20. The trial lasted from 9:10 till 11:30. In the afternoon ropes were tested. A start was made at 2, the load came on at 2:50. The trial lasted from 3:8 till 5:30. The same constancy of voltage was obtained as in the other trial.

* To convert kilogrammes per square centimetre into pounds per square inch, multiply by 14·2. † To convert metres per second into feet per second, multiply by 3·3. ‡ 1 sq. cm. = 0·155 sq. in. § During this trial a revolution counter having omitted to count a certain number of revolutions, which is proved by the negative slip obtained, the figures in column 11 and 15 are minima. Taking the chronometer into account, these figures become respectively 162·95 and 78·49. It is to be observed, moreover, that the engine and dynamo were new, and had only been run previously for two hours, on the eve of the trials. The passive resistances were therefore considerable, as is shown, as a matter of fact, by the results of the fifth trial. ‖ During the last five trials the volts on the Siemens torsion voltmeter were 93·66 in lieu of 94·0, which gave an average of 93·88 for the power instead of 94·0 at the moments of taking the diagrams. ¶ Ten readings out of fifteen were taken at 93·75 instead of 94·0 volts; this gave an average of 93·83 for the power.

After the trials were finished the Commission met together under the Presidency of M. Dubreuil, when the above minutes were read and adopted. M. Bonet undertook to work out the diagrams and to furnish the Committee with his results in the shape of tables, and all the other gentlemen who had taken part in the trials were requested to send in their reports. The hearty thanks of the Committee were accorded to the various gentlemen who had given their assistance in one shape or another, and amongst others a vote of thanks was passed to the stoker for the manner in which he had kept the boiler pressure constant. M. Dubreuil stated that he would ask the Council of the Société Industrielle to strike a medal commemorating the trials which had just taken place.

The accompanying Table recapitulates the general results of these trials. If we examine this Table and neglect the results of the first trial, which did not yield anything certain, owing to one of the counters having got out of order, we shall find that for a constant resistance—

A. The ropes transmitted	160·7 H.P.	with a slip of	0·329	per cent.
B. The Lechat belt	„ 161·9 H.P.	„	0·780	per cent.
C. The Lemaire belt	„ 161·0 H.P.	„	0·961	per cent.
D. The Domange belt	„ 162·42 H.P.	„	0·780	per cent.

The diameters of the pulleys were taken at the surfaces and at the lines of contact. If we reduce these results to 100, and take into account column 27 of the Table, which shows the average load in each trial, we find that—

A. Ropes transmitted	100·0	with	0·1	slip.
B. Lechat belt „	100·87	„	0·237	„
C. Lemaire „ „	100·37	„	0·292	„
D. Domange „ „	101·07	„	0·237	„

Tension of the Belts.

During the trials the sliding base of the dynamo was not made use of for the ropes, but it was more or less employed for the belts, according to the wishes of those who supplied them who were allowed to regulate the tension whilst the trials were in full swing.

Conditions of Trial.

It is evident by the Table that the comparative linear speeds of the belts and ropes, and the pull per square centimetre demanded from the gear, were excellent and identical. Thus, for a linear speed at the point of contact with the pulley of—

20·4 metres per second (67ft.) the ropes transmitted a pull of 11 kilogrammes per square centimetre (156lb. per square inch);

20·49 metres per second (67ft. 6in.) the Lechat belt transmitted a pull of 12·47 kilogrammes per square centimetre (177lb. per square inch);

20·46 metres per second (67ft. 6in.) the Lemaire belt transmitted a pull of 9·45 kilogrammes per square centimetre (134lb. per square inch);

20·51 metres per second (67ft. 7in.) the Domange belt transmitted a pull of 10·97 kilogrammes per square centimetre (156lb. per square inch).

Constancy of Volts.

A peculiarity noticed in the course of the experiments was the steadiness of the needle of the voltmeter when rope-driving was employed, and the oscillation to the extent of one or two divisions when the driving was effected by belts. This oscillation, which at times rendered the reading difficult, corresponded exactly with the passage of the fastening. It did appear to affect the lighting. It shows, however, the necessity for good joints.

Cotton Ropes and various Belts.

Obliged to limit the number of trials, the Committee was not able to experiment on all the other materials proposed, and it decided to limit the trials to such materials as had had at least 15 to 20 years' commercial use. The Committee, however, regretted that it was not able, owing to a misunderstanding, to try M. Domange's homogeneous belt, which one of his representatives had offered from the first to place at their disposal.

Shape of the Pulley Rims.

The shape of the belt flywheel was according to the designs of the firm of Van den Kerkove, of Ghent, and those of the grooves to the designs of MM. V. Dubreuil and A. Dujardin, and were of the kind usually adopted for this kind of work.

General Working.

It should be observed that there was not a single accident during these trials. The dynamo, although new and only just out of the Belfort shops, ran as well as could possibly be desired and without interruption. Not a single lamp was burnt up or injured. The boiler, the fire of which was kept in a marvellous manner by stoker Louis Wagnez, of the Compagnie du Nord, the engine, in a word, all the mechanical apparatus worked to perfection.

Résumé.

The experiments show that ropes and belts well fitted absorb much the same amount of power. M. de Cuyper, however, applied a reservation to the figures in the recapitulatory table relating to the value of the belt slip. According to M. de Cuyper the thickness of the belts should have been taken into account in reckoning the diameters. If this be done the belts have a slip comparable with that of the ropes.

VARIATION OF INTERNAL RESISTANCE OF A VOLTAIC CELL WITH CURRENTS.*

BY HENRY S. CARHART.

It has long been known that the internal resistance of a voltaic cell, when at a constant temperature, has not a fixed and finite value, but that it is a function of the current flowing through it. The methods commonly employed to measure this resistance are not sufficiently exact to exhibit the relationship in question with satisfactory accuracy. But if the condenser method be employed,† together with certain auxiliary appliances to secure very brief and uniform closing of the circuit through different external resistances, while the potential difference between the battery terminals is measured within this short interval, then results can be obtained which plot as a smooth curve.

The resistance measured is a quantity satisfying the equation

$$r = R\frac{E - E'}{E'}, \text{ or } \frac{E}{R+r} = \frac{E'}{R} = I,$$

where r is the internal resistance, E the electromotive force of the cell, and E' the potential difference between the terminals when

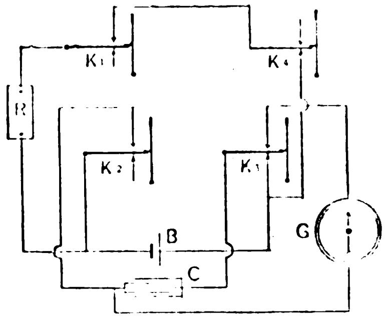

Fig. 1.

closed through an external resistance R. To determine the relation between r and I, the potential difference E' must be measured with different external resistances in succession. For this purpose, the operations of closing the circuit, charging the condenser, discharging through a ballistic galvanometer, and finally opening the circuit, must be done by some mechanical device by which all of them use be repeated in precisely the same interval of time. The disturbing influences due to absorption of the condenser and polarisation of the cell are then as nearly eliminated as possible.

For this purpose I have made use of a pendulum consisting of a long narrow frame pivoted at the top, and carrying a heavy bob at the bottom. The bob swings between two curved rails, concentric with the axis of suspension of the pendulum, and each rail supports two keys, which can be clamped on it in any desired position. A vertical lever on each key holds it closed on the lower contact; but when the pendulum sweeps over the rails it throws these levers over, and allows the spring keys to make contact on the upper point. The contacts are all platinum, and the base and pillars of the keys are hard rubber. When care is taken to adjust the

Digitized by Google

contacts properly, and to keep them free from dust, their performance is in every way satisfactory.

Fig. 1 shows the connections for the measurements in hand. Keys K_1 and K_4 are on one rail, while K_2 and K_3 are on the other. When the lever of K_1 is thrown forward while that of K_4 is up, the battery circuit is closed through the resistance R. When the lever of K_2 is thrown over while that of K_3 is up, the battery is charging the condenser C; but as soon as the lever K_3 is thrown over, the cell is disconnected from the condenser, and the latter is instantly discharged through the galvanometer G. The pendulum swings from left to right on removing a detent. If all the levers are up, it closes the battery circuit on reaching K_1, charges the condenser by throwing over lever K_2, discharges it through the galvanometer by means of K_3, and finally opens the battery circuit on passing K_4. The key levers remain forward out of the way of the pendulum bar as it swings back again to the detent. The keys can be set as close together as desired. The length of the pendulum is such that its period is a second. Hence the time during which the battery circuit remains closed can be calculated. To get the deflection proportional to the total electromotive of the cell, the levers of K_1 and K_4 are both left down. The pendulum then charges and discharges the condenser, the circuit through R remaining open.

The change of resistance with the current is exhibited in a marked degree by "dry cells." The table contains the data of a series of measurements on a Gassner cell, whose electromotive

d	d_2	R	r	I
271	258	400	21·1	0·0028
...	249	200	17·7	0·0056
...	238	100	13·9	0·0106
...	227	50	9·7	0·0203
271	223	40	8·6	0·0249
...	218	30	7·3	0·0324
...	212	20	5·56	0·0473
...	204	15	4·93	0·0607
...	194	10	3·96	0·0868
271	172	5	2·87	0·0538
...	164	4	2·59	0·1838
270	153	3	2·29	0·2289

force was 1·213 volts. The first column contains the deflections due to charging the condenser with the whole electromotive force of the cell, and it will be seen that the polarisation was inappreciable. The second column contains the deflections due to charging the condenser with the potential difference at the extremities of the cell when closed through the resistances in the third column. The fourth column contains the resulting internal resistances, and the last column the currents.

In Fig. 2 these internal resistances and the corresponding currents are plotted as co-ordinates. It cannot be objected that the relatively low resistances with the larger currents are due to polarisation; for, while it was demonstrated that polarisation did occur within the small time interval required for the pendulum to

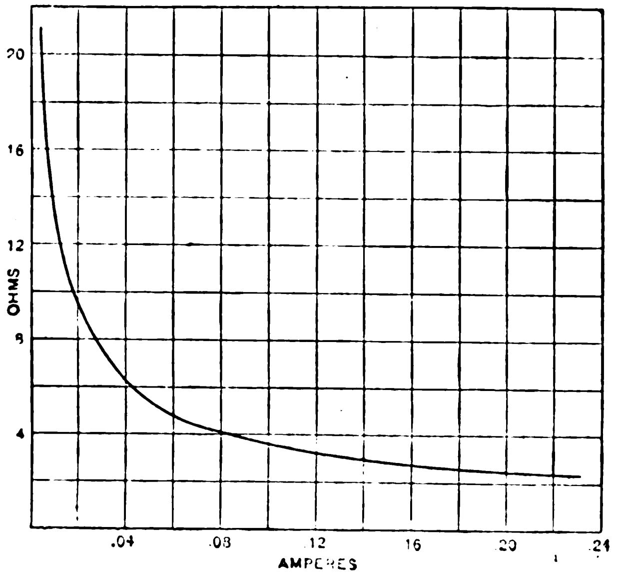

Fig. 2.

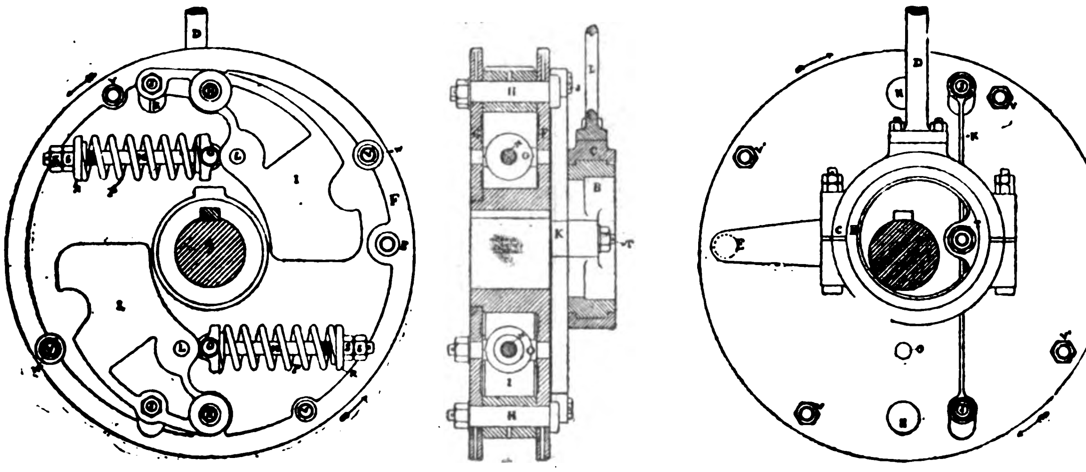
swing from K_1 to K_4, yet the effect of such polarisation is to diminish the potential difference between the terminals of the cell when on closed circuit, and this effect increases the computed internal resistance.

The Gassner cell was an old one, and its internal resistance was above the average; but other dry cells show the same characteristic curve, differing only in the relative values of r. A Daniell cell shows a similar decrease in r with increase in current, but the decrease is much smaller, and the curve is more nearly a straight line.

AUTOMATIC EXPANSION GEAR FOR HIGH-SPEED STEAM ENGINES.

The accompanying set of illustrations shows the construction of the automatic expansion valve gear employed by Messrs. J. P. Hall and Co. in their new steam-dynamo sets. It will be seen that the gear is actuated by a high-speed crank governor, the portion F of which is keyed to the shaft end, while the portion G is an annulus connected by bolts, and distance pieces V to F, leaving an intermediate space in which are contained the weights I and the springs M. The weights are pivoted at H, H, the upper one being provided with a tailpiece whereby the two weights can be connected together by the flexible bar K. Each weight has connected to it, by a stud L, an eyebolt round which is coiled the helical spring M. This eyebolt passes through a swivel lug O, pivoted and free to revolve in the discs F and G. The compression



Automatic Expansion Gear and Crank Governor.

of the springs can be adjusted to balance the tangential force of the weights within a certain variation of speed by means of the locknuts S. The flexible bar K is on the outside of the disc F, and is fixed on to the studs J on the weights. These studs pass through slots in the disc. At the centre of the bar is a forged eye that embraces a stud T on the eccentric B. The eccentric, which has a large eye to enable it to move

Digitized by Google

relatively to the shaft has an extended ear pivoted to the disc at E. When the weights I, I move in or out, owing to variations in the speed of the engine, the flexible bar K shifts the eccentric to vary the cut-off. The governor can be used for either right or left hand by reversing the position of the parts. The cut-off is controlled by variation of travel of a single slide valve, the angle of advance varying with the load. Although this does not give ideal steam distribution, nor as perfect as in more elaborately designed expansion valves, it is possible that it answers its purpose for steam engines of small power.

THE EWING HYSTERESIS METER.

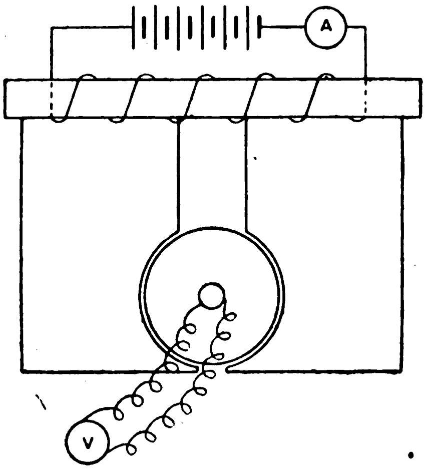
The following is an abstract of the discussion at the Institution of Electrical Engineers on Prof. Ewing's Paper on "A Magnetic Tester for Measuring Hysteresis in Sheet Iron." Speakers who have been good enough to return their proofs revised have their remarks prefaced by an asterisk. Prof. Ewing's Paper appeared in our last issue :—

*The CHAIRMAN (Sir David Salomons), after proposing a vote of thanks, said they had just heard a Paper which would have been most welcome to them three or four years ago, but it was better late than never. He was sure that those who were engaged in laboratories would find such an instrument as that described most valuable, but their appreciation of it would be as nothing compared with that of the manufacturer and engineer. He had recently seen a masterly report (by Prof. Fleming), showing the extreme importance of the quality of transformer iron, and it showed that if the shareholders in an electrical supply company got their bread when the iron was as at present, in the future they might expect to get their meat and dessert.

*Dr. J. A. FLEMING said it was impossible not to admire the ingenious and simple solution of a practical problem which Prof. Ewing had brought before them. He thought it possessed three important recommendations for a workshop method : in the first place it was independent of steadiness ; it worked with small samples, and in the next place it occupied a very short time. No doubt the apparatus had passed through many stages before it had been presented to the public, but he would like to ask Prof. Ewing why he preferred to revolve the specimen and not the magnet. At first sight it seemed the simpler thing to do to revolve the magnet. One thing easy to test in *that* form would be the effect of temperature on hysteresis. It must not be forgotten that the hysteresis losses in iron varied very considerably with temperature. In transformer tests he had found the differences of hysteresis loss in the transformer, taken quite cold and taken at 100°C., as much as 12 to 15 per cent. Then again, although this was not, of course, a suggestion for an improvement, it was an obvious variation to make the field revolve, which might be done in two or three different ways. Again, one would like to be assured that in the use of the instrument the brass clamps holding the specimens together did not have any eddy currents set up in them. It would, of course, be an important application of this instrument to assist to solve that question which had exercised the minds of many of them, whether there was a time increase in the hysteresis loss in iron by use. That had been discussed a good deal in the pages of the technical journals, and many experiments had been made on it. This loss certainly did not occur in all transformers, but it seemed that it did occur under certain circumstances in some. This could be tested by measuring the loss in portions of a transformer core at various times. If iron aged, not as port wine, by way of improvement, but by way of deterioration ; then it was not of much use to wrangle about very small differences at the core loss when large ones might be brought about by use. These were important practical questions, and any instrument which facilitated the solution of them would be of very great value. No one who had used ballistic methods in laboratories was in love with them.

*Prof. CAREY FOSTER said at first sight it occurred to one that it would be possible to deflect a magnet like that so delicately suspended by causing even a non-magnetic body, say, a piece of wood to revolve between the poles ; anything rotating between the poles acting as a fan. Another point was that time lag, or magnetic viscosity, would, he imagined, act on such an instrument like that in the same way as true hysteresis, and it was not obvious that this instrument would distinguish between the two effects.

*Prof. W. E. AYRTON said there was one thing which charmed him about this instrument, especially as it had been made by a Cambridge professor, and that was that an observer had simply to turn a handle ; the instrument, as they could see, had a slot, and if they possessed the necessary penny it achieved the desired result. Certainly if all one wanted to do in testing iron was to ascertain approximately the hysteresis, no better instrument than the one on the table could be used. If, however, one wanted to know the hysteresis for different inductions, was it quite right, as Prof. Ewing had said, to assume that the ratio of the hysteresis of different irons with different inductions was the same? He had rather implied in the Paper that it was so, but in his (Prof. Ewing's) own Paper, published with Miss Klaassen, irons which might be said to have the same hysteresis with an induction of 4,000 varied by 8 per cent. at an induction of 8,000, and by 12 per cent. at an induction of 2,000. There was another point which must not be forgotten, and that was that to the designer of a dynamo or of a transformer hysteresis was not all that he wanted to know. It might seem a roundabout way to measure the permeability if they only wanted to know the hysteresis, but if they wanted to know the permeability—and he did not see how they could make calculations unless they did—it did not seem a round about way of getting hysteresis loss by first measuring the permeability. Then came the question, Could they get the permeability of iron easily, or must they resort to the time-honoured ballistic galvanometer? In the beginning of Prof. Ewing's Paper he rather implied that they could not get the hysteresis quickly by first finding the relation of magnetism to magnetising force. That, however, if he might venture to say so, had not been quite his experience. Some years ago he wanted to see if it was not possible to make an instrument which would enable him to get the B-H curve quite quickly. His object in designing the instrument was to make something which would be acceptable to mechanical engineer students, some of whom worked in his laboratory. The mechanical engineer did not care particularly about the vagaries of a ballistic galvanometer, but appreciated dynamos and motors. So it occurred to him that the simplest plan was to make a little separately excited dynamo, and use the specimen required to be tested as the yoke of the dynamo. The sheet, or rod, to be tested was simply passed through the coil and clamped down, and formed, in fact, the yoke of the machine, which had been constructed under Mr. Mather's supervision (*see* Sketch).



There was an armature of the Paccinotti type rotated by a little motor at a fixed speed. Attached to the brushes was a voltmeter, and there they had the whole apparatus. The ammeter gave the magnetising current, and the voltmeter the corresponding induction in the iron, so that by merely altering the resistance they got in a few minutes a series of points in the B-H curve, which obviously might be obtained between any desired limits of plus and minus magnetising forces. The observation was not taken by the swing of a ballistic galvanometer, but by a perfectly steady deflection. It had the disadvantage, compared with Prof. Ewing's instrument, if they only wanted to know the hysteresis, that they had to take the area of the curve ; but if they wanted to know both the permeability and the hysteresis, then they got both easily. Of course it was not nearly so simple an instrument as the one on the table, and he repeated that, if they merely wanted to make fairly approximate measurements of hysteresis, the latter was certainly the better of the two.

*Prof. G. FORBES said that in transformer work there was no doubt hysteresis was the great thing to look after ; the permeability was good enough in a piece of iron that had little hysteresis. The instrument commended itself to them because it was a thoroughly practical instrument for testing samples that were being used in manufacture. It was essentially, he should say, not a laboratory instrument. While it was admirably adapted for the measurements they wished to make in the shops it was not, he thought Prof. Ewing would admit, the most refined instrument that could be obtained for laboratory work. He thought that Prof. Ayrton had hit upon a point as to the magnetic density. They could not very well trust to hysteresis being proportional in different specimens of irons at different densities. Owing to the enormous hysteresis variations with different samples of iron he presumed that Prof. Ewing considered it quite immaterial whether the strength of the field-magnet diminished with age, so long as it did not become really bad ; so long as it did not fall more that 50 per cent. or so, he supposed he would consider the result practically the same, because they must remember they were always comparing the sample with the standard sample, and that was rather a check on the calibration of the instrument. Dr. Fleming drew attention to the possibility of eddy currents in the brass work, and he (the speaker) would suggest that the eddy currents in the iron itself might possibly also be quite perceptible. If they were they would probably appear immediately upon considerably increasing the speed of the instrument, and if they could vary the speed very largely without altering the values so as to give very erroneous results, he thought that that source of error was probably of no importance. He did think, however, that he would prefer that explanation of eddy currents in the iron rather than the explanation Prof. Ewing gave as the reason why the straight line in Fig. 3, which covered the whole observations, did not pass through the zero. Obviously if the iron were perfectly without hysteresis there would be a certain amount of work done owing to eddy currents at the zero point; that would not be shown by the ballistic method, but would account for the deviation of the straight line from the zero point. The instrument was a perfectly beautiful one, and one for which they had been

Digitized by Google

waiting for a long time. When he heard that Prof. Ewing was getting out such an instrument, and before he knew the method on which it was founded, he recalled the apparatus which Prof. Elihu Thomson made some years ago, and which, he believed, was being made by the General Electric Company of America. Prof. Thomson cut his sheet iron into circles and built them up into a small cylinder, mounting them on a pivot, retaining them in position by a spiral spring. He then rotated, as Dr. Fleming suggested, a field round the iron cylinder, and measured the deflections produced in the cylinder by the torsion due to hysteresis, the restraining force being the force of the spring and the deflection being proportional to the force required to overcome that.

*Mr. A. SIEMENS said he would remind them that he brought some results of hysteresis before the Institution three years ago, where the results were measured by the ballistic method; and he might say that they had still continued, and probably should continue, to use that method, although they would probably obtain some of these instruments of Prof. Ewing's. Prof. Ewing had himself said in the beginning of his Paper that specimens cut from the same plate might vary considerably, and he also said that the treatment of the specimen was of great importance. That was precisely what they had found—that if they wished to determine the hysteresis of any specimen they must not do anything with it. They dare hardly look at it, or it would change its hysteresis altogether. Prof. Ewing said that when he bent his strips into a ring in calibrating his instrument he had to anneal the ring to get back the previous state of the iron; but from experiments they had made he did not think they could get the state of the iron back again by annealing. They had had a very sad experience, and perhaps it might serve as a warning to others. They might remember that he spoke very hopefully of a cable transformer, a transformer to be made on the cable machine, where a strand of iron wire was to be made and spun round with the primary and secondary conductor. They found that it was simply impossible to make this cable transformer sufficiently good as regards hysteresis, because however good the individual wires were which were received from the manufacturers, the mere fact of laying them up in a strand, the mere manipulating of them spoiled them, and the hysteresis increased to such an extent that these cable transformers were of no use whatever. He spoke of this because he wanted to point out what he considered was the only drawback in this instrument, and that was the filing of the specimens. He was perfectly certain that if a millimetre, more or less, were filed, it would at once make the results of the readings quite different. As he said at the commencement, as a rule if very accurate scientific results were required, the ballistic method was the safest. Now Prof. Ewing had reproached that method with being slow and not easily performed. Of course, if they took the man in the street and asked him to take readings on a ballistic galvanometer, they would not succeed; but if they took people who had been educated as electrical engineers, who had passed through the electrical testing room, and who knew how to read a galvanometer, they could make those tests very quickly, and he would say that with the apparatus as arranged in his firm's works the readings of a specimen could be completed in half an hour.

Mr. S. Z. DE FERRANTI said the beauty of the instrument shown and its perfect adaptability for the purpose for which it was most generally required, namely, the testing of transformers, so much impressed itself upon his mind that he was immediately seized with a desire to know where it was made, where it was on sale, and how much it could be bought for; but this idea was rather dispelled when Prof. Ayrton came along and showed them another instrument. He immediately thought it might be necessary to have both. He thought, however, from the various remarks made by the different speakers, that the instrument which Prof. Ewing had shown, coupled with the accurate means of reproducing samples without varying the class of treatment, would serve the purpose most perfectly for everything one could want in the way of transformer work. He would suggest it would be more accurate to properly stamp the sample than to cut it, which involved a certain amount of bending.

*Mr. W. B. ESSON said he thought it was only a manufacturer who could appreciate at its true value an instrument like Prof. Ewing's. Although it was very true, as Prof. Ewing would admit, that it did not give tests of the same scientific accuracy as the ballistic method, he could conceive no instrument more adapted for rapid pass tests of bulk iron, such tests as were required in the factory.

*Mr. F. G. BAILY said he had been trying some experiments with a rotating magnet for a somewhat more scientific purpose than that of Prof. Ewing, and it was with considerable disappointment that he found that Prof. Ewing had applied the principle so satisfactorily for a useful purpose, whereas he (the speaker) had not. There were one or two points about which he should like to make inquiries. As regards the immaterial thickness and size of the plates, it was quite easy to see how the induction of the iron stayed constant, but he could not quite see how the total hysteresis in that sample stayed constant. He would like to ask Prof. Ewing whether he had considered the effect of self demagnetisation while the sample was at right angles to the poles of the magnet. When it was away from the poles, before it got to the other poles, it must demagnetise itself; it was only a short piece of iron, and there must be a certain amount of demagnetisation, and therefore the repulsion when it got to the opposite pole would be diminished, the decrease depending on the retentiveness of the iron, and he thought that was a possible explanation of the variation of the line in Fig. 3.

*Mr. A. P. TROTTER said he did not quite understand whether or not Prof. Ewing annealed the specimens. The specimens seemed to be so much smaller than those used by most people in testing iron, and he thought that the hardening of the hedges by shearing ought to be allowed for.

*Prof. EWING, in replying, said Dr. Fleming had asked why he had selected a form in which the specimen revolved rather than the magnet. The point he mentioned was a very important one, and was, in fact, very carefully considered in the early experimental stages of the instrument. At one time it had been definitely decided to use a revolving magnet and a fixed specimen. If the specimen were made to be the stable body, which indicated a deflection through the rotation of the field-magnet, then, of course, it would be necessary that the specimen should always have precisely the same amount of mechanical stability. Now, in putting specimens into a carrier it was not a little difficult to ensure that they would have always the same amount of mechanical stability. The stable part should be a thing which did not have to be handled, and the parts of which did not have to be varied. That was the principal thing, but there were several other minor considerations into which it was not necessary to go. Another point which had been raised by Dr. Fleming, and also by Profs. Carey Foster and Forbes was the influence of eddy currents and fan action on the deflection. As regards fan action, one could easily see that there was no material effect by turning the carrier round when the specimen was one of wood or vulcanite. After all, the magnet, although it had not a large amount of stability, was not so very delicately poised as they might think. As regards eddy currents, he thought he had mentioned sufficiently fully in the Paper that when the speed of the revolving sample was increased, even to the extent of about doubling it, beyond the speed necessary to get a steady reading, they did not find any appreciable increase in the amount of the deflection, and to his mind this was quite sufficient proof of the unimportance of the eddy currents, seeing that their effect would increase in proportion to the square of the speed. He should add that the brass work was made with the view of diminishing eddy currents in it as much as possible. Dr. Fleming spoke of the laboratory uses of the instrument, and he was very glad he had done so, because several others seemed to be rather under the impression that it was a workshop instrument, and nothing else. Primarily, of course, it was a workshop instrument; but he must confess that during the last two months he had found it a very interesting laboratory instrument as well, and he thought it would be found so by others. Only the other day the manager of a central station asked him to test a sample of iron taken from an actual transformer used in the station system for several years. He was distinctly unwilling to apply the ballistic method to it, on account of the time required; but in a few minutes he had cut this iron into a number of strips, put them into the machine, tested them, and found they were very bad indeed. He then had the curiosity to anneal these same specimens, and the effect was to remove just 49 per cent. of the hysteresis, leaving 51 per cent. of it. Whether this meant that that particular iron had been put into the transformer unannealed, as was probably the case, or whether the use of the transformer during the years it had been employed had had the effect of deteriorating the iron to that extraordinarily large extent, he was unable to say. That was only one question which might be cited to show that there were many questions that might be quickly and easily answered with an instrument of this sort which could scarcely have been answered in any other method of testing, except by a much larger expenditure of time and trouble, and he looked forward to making inquiries into a subject which had engaged the attention of Mr. Mordey and others—the influence of prolonged heat on iron. A point mentioned by Mr. Siemens was whether successive annealings of iron always brought the iron into the same physical condition as regards hysteresis. His own experience was that as long as the annealing was done in the same way, by holding the specimen in a gas flame for a few minutes and by cooling in the air, it did produce the same result each time, but he could quite believe that annealing in a furnace and keeping the iron hot for a long time might have a very different effect indeed as regards hysteresis from that which annealing in a small gas flame would have. Prof. Ayrton was quite right in saying that the ratio of the hysteresis at various inductions was not absolutely the same in all specimens of iron. He (Prof. Ayrton) had quoted some figures which the speaker at that moment was unable to verify, from the Paper published jointly by himself and another some years ago. The 8 per cent. alluded to, he thought, must have been between extreme cases, and not between the general mean and any individual case. The general mean table of figures which he had given that night was an embodiment of a much larger number of tests than those mentioned in the Paper referred to by Prof. Ayrton. It included a large number of somewhat recent tests, and referred more particularly to transformer iron, and not to other sorts of iron. Again, Prof. Ayrton had said that the hysteresis was not all that was wanted. Now, as regards transformer work, he ventured to think it was hysteresis that was wanted, and practically nothing else. It was true that there was no very precise relation between hysteresis and permeability beyond the fact that if they had a sample with very little hysteresis they might safely take its permeability for granted: that expressed the general position of the transformer maker. Prof. Ayrton described a convenient instrument of his own and Mr. Mathers, which might very possibly facilitate the testing of iron if one wished to get the B-H curve and measure its area in a manner similar to the ballistic. Prof. Ayrton said that if they took the B-H curve the thing was done. It was not done at all. When they got the B-H curve, after a good deal of solid work, they then had to take the results home and reduce them to absolute values, draw the curve, and measure the area. That method did not commend itself if the information that was really wanted could be got by turning a handle. He was very much interested in Prof. Forbes's notice of Prof. Elihu Thomson's instrument, which seemed to be of a very similar character to the experimental apparatus used with such remarkable success by Mr. Baily in establishing his very important discovery regarding the disappearance of hysteresis in a revolving field at very high inductions. Mr. Siemens raised a very important point in saying he would hardly dare look at a specimen without altering its hysteresis. It was perfectly true that it was most difficult to deal with iron in any way without producing some effect, sometimes a large effect, on its hysteresis. He thought probably anyone who wanted to use this instrument would punch his specimens to the exact size he wanted, and treat them in the same way as

Digitized by Google

transformer stampings were themselves treated. But Mr. Siemens seemed to exaggerate the difficulty of preparing the samples. Many of those samples were not annealed after being cut, and were not materially deformed in cutting. The samples which had to be tested should as far as possible be tested in the same state as the stampings they were intended to represent, and should be subjected to the same treatment.

PARLIAMENTARY INTELLIGENCE.

SELECT COMMITTEE ON THE TELEPHONE SERVICE.

The Select Committee resumed its sittings after the Easter recess on Friday, Mr. Arnold Morley, the Postmaster-General, presiding. At the outset of the proceedings the Chairman announced that the Committee had decided to postpone taking expert evidence until after the general evidence had been given.

Mr. W. H. DICKINSON, Deputy Chairman of the London County Council, gave further evidence as to the views of that body in regard to the Agreement between the Telephone Company and the Government. After lengthy observations bearing on the Agreement and therefore strictly speaking outside the scope of the Inquiry the WITNESS proceeded to complain that the telephone system in London was certainly not good, which was admitted some time ago by the Chairman of the Company himself, though no doubt since then it had improved. Complaints had been very generally made about it, and he handed in a letter recently received from the Vestry Clerk of Battersea. The result was that the telephone system was not taken up in London to anything like the extent that it was taken up abroad. In London there was only one subscriber to 540 of the population; in Edinburgh, 1 to 240; in Amsterdam, 1 to 237; in Rotterdam, 1 to 214; in Brussels, 1 to 192; in Paris, 1 to 187; Rome, 1 to 180; Vienna, 1 to 177; Dresden, 1 to 84; Copenhagen, 1 to 83; Berlin, 1 to 66: Christiania, 1 to 36; Zurich, 1 to 33; Stockholm, 1 to 22; in fact, London stood well ahead of the principal towns of Europe in deficiency of telephonic accommodation.

The CHAIRMAN: Do you think that is at all due to the fact that London has a far better telegraphic and postal service?

The WITNESS said it was due to two facts—first, that the telephone service was not so good in London, and also that it was more expensive. In London the charges were £20 subscription per year, or £17. 10s. for a five years' agreement, and with this he proceeded to compare the charges in other Continental towns, but

The CHAIRMAN said that information was already before the Committee.

Sir J. GOLDSMID asked what were the charges in American towns.

The WITNESS said that in the American towns they were much more expensive. In New York, he believed, the charge was £30, and in Chicago, too, it was very high. In order to ascertain for how little it could be done in London, the Committee of the Council had obtained separate reports from Mr. Binnie, their engineer, and also from Mr. Newland, a telephonic engineer, and Mr. Bennett. Mr. Binnie's report was that a service could be supplied to 10,000 subscribers in London at a capital expenditure of something under £400,000, the annual charge on which, including the redemption of capital, would be covered by a charge of £10 to each subscriber. Mr. Newland's report was that the capital expenditure would be £366,000, representing an annual charge of £75,398, which would work out at less than £10 a year. Mr. Bennett's report made the annual charge, including redemption, renewal, depreciation, and royalties, £76,793. That was intended to cover the area of the County of London—not outside.

The CHAIRMAN: That would be a much smaller area than the National Company now supply.

The WITNESS: Yes; it was within what was called the London district, extending to Kingston. The Council having arrived at that point, therefore thought that London ought to be served with telephones at £10 a year subscription.

The CHAIRMAN: I suppose you are aware that a large portion of London is telephoned at £10 a year now; that is, that private houses on a five-years agreement get their telephones at £10 a year?

The WITNESS said that he was under the impression that that was only where the subscriber had an instrument of his own. Having investigated the accounts of the Telephone Company, the Committee came to the conclusion that the reason, to a great extent, why the charges were so high was the very large capital of the Company. On December 31, 1894, it was £4,419,455. The proportion of gross revenue from rentals had very much changed of late years. In 1889, when the capital was £864,000, the gross rentals amounted to 40 per cent. of the capital expenditure; in 1893 they were only 15 per cent. In the United Company, in 1887, the rentals were 44 per cent. of the capital expenditure in London, the United Company having been almost exclusively confined to London, but after the amalgamation the rentals only represented 15 per cent. of the capital expenditure. He compared that with Christiania, where, with a charge of £4. 8s. 11d. per annum, their gross rentals amounted to 26 per cent. of the capital. London was placed in a much worse position by the amalgamation; if the United Telephone Company had gone on working as it was then, London might have expected some diminution in charges. The year before they amalgamated the total profit of the Company was £94,264, which, on their nominal capital of £900,000, was 14 per cent.; but as the National Company paid £1,484,000 for that £900,000 worth of shares, it was now represented as a capital of £1,484,000, paying a dividend of something under 5 per cent. Therefore, instead of two companies doing good business, they had an enormous Company paying a dividend of only 5 per cent., which was not likely to give any reduction in its charges. The only way to bring about a reduction of charges was again to place the National Telephone Company under some kind of competition, but the effect of the agreement was to do away with competition.

The CHAIRMAN: Whereas competition in the past has brought the National Telephone Company into a position which necessitates their making heavy charges, you would reintroduce competition in order to reduce them.

The WITNESS said it depended upon what the position of the Company would be in 1911, and competition would undoubtedly result in the Government being able to take over the telephone system at a sum which would not be exorbitant.

The CHAIRMAN: Or rather two telephone systems.

The WITNESS said there would be nothing to oblige the Government to take them over unless the people wanted better accommodation, and that would be given by taking over one system. He contended that if the National Telephone Company was to go on with the benefit of the Agreement, any other authority who said they were ready to do it at no unreasonable expenditure should have the permission of the Post Office to carry out a telephone system.

Replying to Sir James Fergusson, the WITNESS stated that in the event of municipal licenses being granted the municipal exchanges should be placed in connection with the National Telephone Company's exchanges in different towns, and he quite agreed that the Company should receive some payment, but the question of terminal charges should be left to agreement.

In reply to Mr. Snape, as to the service which would be rendered on the estimates which the Council had obtained, the WITNESS stated that the service would be within a restricted area, and though it was probable that they would take in places like Kingston and Epsom, they would have to make a higher charge for those places, and treat them as if they were on the trunk lines. The amount of telephonic business done inside the County of London was vastly large in proportion to that done in the outlying places of the metropolis. In the estimates way-leaves had been taken into consideration, but a good deal of the wires would be underground, and no way leaves would then be paid. An entire underground system, he understood, would be much more expensive.

Mr. SNAPE asked how it was that a company started in Manchester could work at £5, and the most favourable estimate the Witness could produce for London was £10.

The WITNESS said the question of way leaves in London was a serious matter, and altogether it would be more expensive.

Sir JAMES FERGUSSON said he did not know how Mr. Snape got at the figure of £5 for Manchester. He had just come from that town, and they told him there that the charge was £10.

The WITNESS said that the charge of £5 was that of the Mutual Company. In further reply to Mr. Snape, he stated that the more powers the National Telephone Company got the more expensive it would be to buy them in the end. He was quite agreeable to other Corporations outside London having powers to provide telephonic communication.

Mr. RANDALL: What you contemplate and desire is that the London County Council should have a telephone system in London?

The WITNESS said that he was not at liberty to say that the Council desired, but it was his own personal opinion that it would be desirable, if anything was to be done to prevent a monopoly, to have competition from municipal authorities. Within the four-mile radius from Charing-cross there were 7,000 subscribers, and 95 per cent. of the metropolitan subscribers were within the six-mile radius.

Sir JULIAN GOLDSMID pressed the Witness as to whether he represented himself or the Council when he expressed the wish to have municipal telephones.

The WITNESS said the Council had not come to that conclusion. The Council were not the road authority in London, and would, therefore, have to get permission to break up the roads as well as to fix wires to private houses. If municipal licences were granted to twenty places he did not think it would be more difficult for the Government to take over the telephones; they would have to make 21 contracts instead of one, and for that reason they would do it cheaper.

Replying to Sir C. Cameron, the WITNESS said that the system of the National Telephone Company had not been so skilfully laid out as a new system could be laid out; and, assuming a private company or the municipality laid out London for telephone purposes with careful design, when the Government came to take over the system it would make a better bargain by taking over the new company. In fact, that was what he meant by saying competition would be useful. He was in favour of the Government taking over the telephones, but he did not think that question had been considered by the Council. He thought the competition between the telephone and the telegraph was keener in London than elsewhere. The idea had not occurred to him of the possibility of the Government taking over the telephone service for London without waiting till they took over the service for the entire country. He believed all the three estimates he had quoted were based on different systems, but they contemplated absolutely the newest instruments and twin wires.

Sir C. CAMERON: You would give them the newest system of wiring, the newest transmitters, and probably time-meters, to allow a man to pay a certain fundamental charge, and then pay so much for every five minutes he used the instrument.

The WITNESS said he could not say if that would be so. Competition in Birmingham, Manchester, Liverpool, and London would compel each company to give the greatest facilities and accommodation that could be obtained. Assuming the Post Office adopted the policy of encouraging competition, with a guarantee against buying up the companies, he thought that might meet the purpose.

In reply to Mr. John Ellis, the WITNESS stated that the County Council had not received any evidence as to the inadequacy or inefficiency of the service before arriving at its conclusions, but it was the general feeling that it was inadequate

Digitized by Google

Mr. JOHN ELLIS: In Parliamentary Committees we require something a little more definite than that.

Replying to the Solicitor-General, the WITNESS said that he contemplated that municipal licenses should be granted for a term of years and not permanently, and he thought it advisable that they should be terminable at the same date as the Agreement with the National Telephone Company. Even if the licence was granted, the County Council would have to go to Parliament for statutory powers.

Sir E. CARBUTT, as a member of the Council of the London Chamber of Commerce and of the Special Committee appointed to consider the telephone question, said that the Chamber consisted of 6,000 members, and though at the present time Sir Albert Rollit, M.P., who was President of the Chamber, happened to be a Director of the Telephone Company, he had taken no part in the discussions on the question. The gentlemen who formed the Committee were, besides himself, Mr. Emile Garcke (Chairman of Committee), Chairman of the Electrical and Allied Trades Section of the Chamber, Managing Director Electric and General Investment Company; Major S. Flood-Page. Director of the Edison and Swan United Electric Light Company (Limited); Major-General C. E. Webber, C.B., Chelsea Electric Light Company, Past President of the Institution of Electrical Engineers; Mr. A. R. Bennett, New Telephone Company (Limited); Mr. James Chambers, Vice-President of the Chamber; Mr. Henry Clarke, L.C.C., Messrs. Mander Bros., Gracechurch-street, E.C.; Mr. R. E. Crompton, President of the Institution of Electrical Engineers; Mr. W. E. L. Gaine, General Manager, National Telephone Company; Mr. David Howard, Messrs. Howards and Sons, Stratford, E. The resolutions at which the Committee had arrived were as follows:—

1. *Acquisition of Telephones by the Government.*—"That this Chamber, whilst favouring private enterprise, is of opinion that if greater development of the telephone service which the commercial community demands can be better secured by the State acquiring and working the whole system of telephones, then this Chamber would approve the adoption of such a course."

2. *Validity of Telephone Agreement.*—"That the late Chancellor of the Exchequer and the present Chancellor of the Exchequer having in their places in Parliament stated that the Agreement between Her Majesty's Post Office and the National Telephone Company was a binding agreement, it would be useless and a waste of time on the part of this Committee reopening the question at present."

3. *Competing Systems.*—"That properly controlled competition should be encouraged providing that intercommunication between different systems covering the same area can be satisfactorily arranged and subject to the Post Office authorities deciding after due and adequate inquiry that the public can be better and more economically served than by the existing arrangements."

4. *Standard Regulations.*—"That in the opinion of this Chamber it is desirable that standard regulations should be drawn up by a Government Department for the guidance of Local Authorities in determining the conditions to be imposed by them as a preliminary to their consent being given to telephone companies obtaining statutory powers."

5. *Varying Rates for Limited Services.*—"That the desirability of developing the principle of varying rates for limited services should be emphasised by the evidence before the Select Committee."

6. *Unprofitable Areas.*—"That in granting licences precaution should be taken to avoid the neglect of telephone service in relatively unprofitable areas."

He urged that the service should be so extended by the granting of powers in restricted areas, that in the residential districts, where people could not afford to keep servants to go out and do their errands, they should be connected with the shopkeepers and pay 3d. a day, or 2s. a week, for the use of the telephone. At the present time a tradesman had to send his cart round and wait for orders, and there was a large loss of time. Then in the agricultural districts a number of farms might be connected with a central creamery, and it was estimated that 20 farms might be so connected at a cost of £100. In the grant of new licences precautions should be taken against the profitable areas alone being occupied and the unprofitable areas being left without a service; but, of course, such conditions could not now be arbitrarily imposed upon the National Company, which had its licence for 17 years. He did not suggest that the persons living within the "profitable" areas should pay extra so that those in the "unprofitable" areas should get the benefit of the service; but upon being pressed by Mr. Ellis said he did not see how it could be done otherwise. What they proposed was to leave it to the Postmaster-General when a company applied for a certain district to say that both the profitable and unprofitable areas of that district should be supplied.

Replying to Mr. Randall, he said that, as far at he knew, the Chamber of Commerce had never applied to the National Company to reduce its rates. They wished also to adopt the principle adopted in the Light Railways Bill of avoiding going for an Act of Parliament or a Provisional Order, giving the County Councils power to arrange the matter. Of course, the question would ultimately rest with the Postmaster-General and the Board of Trade. He would not like to give an opinion as to whether the charges made by the trunk lines were excessive.

In reply to the Solicitor-General he said that by the resolution as to varying rates it was contemplated that in the same area there might be different grades of subscribers, so that one man might be able to telephone within a distance of one mile and another within a distance of two miles; one set of subscribers in a suburb like Balham might be able to telephone to the local butcher, and another set might be able to telephone to London.

The SOLICITOR-GENERAL: Have you considered at all all the inconveniences which would arise in the administration of the service under those conditions?

The WITNESS said that it was present to their minds that there would be inconveniences, but they did not discuss them. He admitted that there would be very serious inconveniences. In their third resolution they thoroughly appreciated the difficulty which would arise in competition as to intercommunication between different systems, and they discussed that question over and over again, but they had not been able to solve the difficulty.

The CHAIRMAN asked, with reference to the question of profitable and unprofitable areas, whether the Witness was aware of applications having been made to the National Telephone Company to provide telephones, and of those applications having been refused in consequence of the area being unprofitable.

The WITNESS said he had no knowledge of any, and it was only with reference to future schemes that that resolution was put in.

The CHAIRMAN: Would that not result in a new company being seriously handicapped in its competition with the National Telephone Company?

The WITNESS: Not more so than the National Telephone Company is handicapped when it has an unprofitable area. With a smaller capital no doubt even a new company would be able to compete with the National Telephone Company.

The CHAIRMAN: You think the advantage derived from having a smaller capital would compensate for the disadvantage of having an unprofitable area?

The WITNESS: I think it would.

Major FLOOD-PAGE, a member of the Special Committee of the Chamber of Commerce, also gave evidence stating that there was a great deal of divergence of opinion among the members of the Committee, and the resolutions agreed to were a compromise. There was very little difference of opinion on the fourth resolution, but the subjects involved in the others were matters of hard discussion. The governing principle of the first resolution was that they felt that everything should be done for the development of the telephone by the State, which held the monopoly. The telephone had developed enormously in the last 16 years, but when they compared the progress it had made in other countries we were far behind many other parts of Europe in the application of electricity. During the next 16 years no doubt it would increase immensely, and the commercial community, including the small traders, would derive advantage from it; and the view of the Committee was that if the development could be better secured by the State doing it, then they would approve of the State doing it.

The CHAIRMAN said that he understood that the Committee had not expressed any decided view in favour of competition, but that its approval of competition would be subject to the two considerations stated in the resolution.

The WITNESS stated that that was a matter of great controversy, of which the resolution was the outcome. If the Post Office, after due and adequate inquiry that the public could be more economically and adequately served by competition under control, which should guarantee satisfaction, they would entirely approve of it; but if that could not be obtained they would leave it where it is. They thought it of very great importance that standard regulations for the guidance of Local Authorities should be drawn up so that there might be a uniform system all over the country. In considering the question they had assumed that the Agreement between the Company and the Government was an existing and binding one, and he did not suggest that the standard regulations should be arbitrarily imposed upon the National Telephone Company, which at present had its licence for 17 years. All the suggestions were alternatives to the Government themselves acquiring the telephones. As to the question of varying rates it was a matter of notoriety that there were at present varying rates; there were something like ten or a dozen places in London where they had a different rate for local service, and if there was competition that system could be very much extended.

The CHAIRMAN: But would you suggest, even without competition, the National Telephone Company might be induced to extend the service in that direction?

The WITNESS said that it was a matter of common knowledge that nearly the whole of the south of London was dealt with in that way. He contemplated that the telephone would in the future be considered as much a necessity as gas, and therefore he thought if an area was handed over to an Authority or Company, it should not be allowed to pick out the profitable portions and leave the unprofitable portions unserved.

The CHAIRMAN: Do you mean that there should be a uniform system of telephones supplied to every applicant at a uniform price at his own house, or that facilities should be given in the shape of a call station within easy reach?

The WITNESS said it was not for him to say in what shape the facilities should be given, but they contended that some facility should be given to a man to use that for which he was called upon to pay. They also considered that no one should be permitted to take out a licence, and then to drop it, but should come under an obligation to carry it out. The community had suffered very much from that in connection with the electric light.

Replying to Mr. Snape, the WITNESS said there should be means of intercommunication between different systems covering the same area, and means of getting on to the trunk wires, but they did not lay down any plans as to how that was to be carried out.

Mr. H. M. BATES, principal clerk in the office of the Commissioners of Sewers, also gave evidence, complaining, from his own experience, that the service in London was very inadequate and defective; the general opinion was that the single-wire system was radically wrong, and that the defects were caused to a great extent by circumstances over which the Exchange people had no control. To show the view held by the Commissioners of Sewers, he stated that in 1893 they had before them an application to consent to a proposal to apply to the Postmaster-General to establish a

Digitized by Google

first-class double telephone service, and they resolved to allow certain tubes belonging to the City of London Electric Lighting Company to be used on condition that double wires, and all the latest improvements should be supplied at £8 per annum, and the negotiations with the Electric Lighting Company for the use of the tubes were still pending. On the 26th of last March the Streets Committee passed a resolution affirming that the provision now made for the telephone service in the City of London was inadequate, and that telephones should be supplied at a rental not exceeding £10 per annum. They arrived at that price after comparing the charges made in the United Kingdom and in foreign countries, but it was not based on any actual investigation.

Replying to Sir Charles Cameron, he said the Commissioners had not expressed any opinion on the question of applying for powers themselves, or on the question of competition. Their only interest was to get a service as good and cheap as possible.

In reply to the Chairman, he said that the use of the tubes could not be granted without the sanction of the Board of Trade. He could not express any opinion as to whether they were laid in the right direction for telephone purposes, or whether the tubes themselves were suitable for that purpose.

The Committee held another sitting on Tuesday, Mr. Arnold Morley again presiding.

Mr. BERRIDGE, a member of the Streets Committee of the Commissioners of Sewers, was examined with reference to his experience as regarded the efficiency of the service. In reply to the Chairman, he complained that it was very inefficient, as the lines were frequently blocked, and at other times they could hear other people speaking. His own instrument was three-quarters of a mile from the exchange.

The CHAIRMAN: Did you learn from the Company that there was a difficulty in getting a junction wire?

The WITNESS replied in the negative; he was simply told that the line was engaged. Up to last year he paid £20, but he had now got a five years' agreement at £17. 10s. a year. If he wanted an additional wire to his private house, they would charge £12 per year extra. It was his opinion that the charges were excessive; they paid the same rate now as they did 12 years ago, notwithstanding all the improvements. The New Telephone Company supplied at £13 a year.

The CHAIRMAN: They did not actually supply it.

The WITNESS: No, because the National Telephone Company, in their wisdom, bought them up.

The CHAIRMAN asked if he was aware that the larger the number of subscribers the greater was the cost to the Company, and therefore that they were obliged to charge more?

The WITNESS said he thought the greater the number of subscribers the greater the profit, for if a man increased his business the greater the profit. He had no evidence to give on behalf of the Commissioners of Sewers, except that they were very anxious to have a good service at a reasonable rate, and that they had passed a resolution that they thought £10 would be a reasonable rate, in connection with allowing the use of the tubes of the Electric Lighting Company. He was not aware whether those tubes were suitable for telephone purposes, or whether their position or direction was suitable for exchange purposes.

The CHAIRMAN: Are the Commissioners of Sewers contemplating a system of their own, and asking for a licence?

The WITNESS said they did not, but they certainly thought they should have a right to apply for one. At any rate, he considered they should have an absolute veto as to the use of the streets, but he preferred that the Government should take over the whole concern.

The CHAIRMAN: Would you contemplate with satisfaction the City of London taking over a licence for the City and the London County Council having another licence within their jurisdiction?

The WITNESS said he would. He did not think there would be any danger in having different systems inside and outside the city, because arrangements could be made as the railway companies did for the use of each other's lines.

Replying to Sir James Fergusson, the WITNESS stated that he had not had any experience of a superior system of telephoning, and admitted that the interruptions which he had spoken of might be incidental to any possible system in a crowded city. They experienced great interruption a few years ago, when they were without the telephone for a month or two. That was occasioned by a snowstorm, and would be incidental to any overhead system.

Replying to Mr. Benn as to whether the New Telephone Company did not in a very short time secure a considerable number of subscribers, the WITNESS said that it did, of whom he was one. He would be prepared to put up with the inconvenience attending competing systems to get cheaper communication. People would not pay £20 a year for what they could get for £15. The New Telephone Company offered a better system of double wires, and he considered it a grievance that that better system at a lower price was lost by the amalgamation. If the City were to join hands with the London County Council to have, independent of the trunk-wire system, a local system for London, he thought the citizens would willingly put up with the inconvenience of two systems in order to secure a good local system with double wires.

By Mr. John Ellis: The Commissioners of Sewers had not informed themselves as to the number of subscribers within their area, nor of the number of complaints within any given time of the imperfections of the service. From his own experience the complaints might be numbered by scores, if not by hundreds, but he did not know if those complaints had been lodged with the Company.

In reply to Sir James Fergusson, he admitted that there might be difficulty in regard to competing systems in the City area by the multiplication of wires and the taking up of the streets, but said he supposed nearly all new wires would be underground. The City of London had at present nearly as many wires under the streets as they could stand, but he did not consider that an insuperable obstacle.

Mr. JOHN ARCHIBALD DOW, a coal master of Glasgow, said that he had had experience of the telephone in Glasgow for nearly 11 years. The service supplied by the National Telephone Company there was a good one; although there was an occasional breakdown, taking it all over, through and through, it was a very good service. Having the service outside the municipal boundaries was a great advantage, because it enabled them to communicate directly between the business office and the collieries. He did not think it would be an advantage for the Corporation to carry on the business of telephoning within the City, because they might have the pleasure of paying a double rent. If he wished to speak to Greenock, Paisley, or Hamilton through the circuits which the Corporation had put up for themselves, it would be one eternal nuisance, and if any mistake were made they would not know whom to complain to. He regarded the municipalisation of the telephones as a retrograde movement, as it would make a shuttlecock of the customers who corresponded outside, and he would rather see them go into the hands of the Government altogether. In Glasgow the charge was £10; as he had 10 or 12 instruments he paid fully £100 a year, and considered that he got good value for his money. Unfortunately he had no shares in the Company.

In reply to Mr. Benn, he said he came before the Committee at the request of the Telephone Company. He did not think the popular feeling in Glasgow was in favour of municipalisation. The evils of a monopoly could be avoided by fixing a maximum rate.

Replying to Sir James Fergusson, he said that his collieries were distant from Glasgow 10 or 15 miles, and although they occasionally had to wait till the lines were clear, it was for seldom more than five minutes. Occasionally it made him a little angry, and although he had a very hasty temper as a rule, he had never gone so far as to throw the instrument into the street.

Mr. ROBERT CAIRD, superintendent of the Glasgow Omnibus Company, said that they had 32 instruments in operation in connection with the National Telephone Company, 90 per cent. of which were inside and 10 per cent outside the municipal area. The effect of the restriction of telephonic enterprise within the city limits would have a very bad effect upon their business, as it would cut them off, and they would have no communication with their outside offices. The work was very well done by the present Company, and he did not see why the Corporation should take it in hand at all. They had occasional difficulties; they called up all their offices at eight o'clock in the morning to find out if the wires were all right, and if not they had found the Company very prompt in remedying any defect.

Mr. Benn cross-examined the witness as to the friction which had existed between the Corporation and his Company in relation to the Corporation having the tramways in competition with the omnibuses; but the WITNESS asserted that his evidence was entirely uncoloured by any differences between them, and that he had no desire to thwart the action of the Corporation.

In reply to the Chairman, he said that if the result of the Corporation having a system of their own, and having entire control of the streets, was to drive the National Telephone Company out of Glasgow, he would not like that at all, and considered that it would be detrimental to the interests of Glasgow.

Mr. J. P. WALDIE, colliery owner, of Edinburgh, who had been a subscriber to the National Telephone Company since it started 18 years ago, said he paid £142 a year for the service. His experience of its working in Edinburgh was very satisfactory, though there were occasional difficulties and breakdowns, but complaints had been met fairly promptly. He was also opposed to the suggested system of municipal licences.

Mr. A. RIACH, a journalist, and editor of the Edinburgh *Evening Despatch* concurred in this evidence. In reply to Mr. Lawson, he said he was at first inclined to favour municipalisation as a means towards nationalisation, but having more fully considered the matter, he could not see how it would be effectual, even with a very wide area. Certainly, if confined within the boundaries of Edinburgh and Glasgow, he did not see how it would work at all. Replying to Mr. Benn, he said he doubted very much whether the ratepayers would view with satisfaction the municipalisation of the telephones, as they looked upon the acquisition by the Corporation of the electric lighting as rather a hardship. The poorer portion of the population would certainly be averse to it, as they looked upon the telephone as a luxury which should be paid for by those who desired it.

Mr. A. H. MONCUR, ex-Provost of Dundee and Deputy Chairman of the Harbour Trust, said he was thoroughly conversant with the commercial requirements of Dundee and the neighbourhood, and had been for 10 years a subscriber to the telephone. He objected to the nationalisation of the system, as he considered that where there was an efficient service, as there was in Dundee, it should be left alone. He was chairman of the local telephone company previous to its amalgamation with the National Company.

The CHAIRMAN: How do you compare the telephone service now with what it was when there was competition in Dundee?

The WITNESS said he considered it was better, for the reason that under the competitive system the town was divided, one-half being upon the local system and the other upon the National system; consequently, if they wished to be in communication with the whole town they had to get an instrument from each Company, and, after all, the service was not so efficient as at present. The Company now charged £8. 10s. for the first instrument, with a deduction of 15 per cent. if more instruments were taken. The National Company, before competition arose, charged £20, and the local company started at £10. The result of the competition was that the National Company brought down their charges to £5, and the local company had to follow, their lowest price having been £5. 10s. A sub-

Digitized by Google

scriber who wished to be in communication with all other subscribers had to pay £10. 10s. for a service not so good as they now got for £8. 10s. His opinion of the effect of competition was not favourable, except in the way of bringing down prices. The local company paid good dividends, beginning at 9 per cent., but the last dividend was only 5 per cent. Just before the amalgamation took place the Company were contemplating raising another £5,000 capital, the original capital having been £5,000. When the National Company took over the local company they reconstructed the system to a large extent throughout Dundee. As to the future of the telephone system, he thought it should be nationalised; but, short of that, he would prefer to see it in the hands of a strong company. He was distinctly against the system of municipalisation.

In reply to Mr. Benn the Witness stated that the National Company bought up the local company at 40 per cent. premium, and the purchase agreement provided that the citizens of Dundee should not be charged more than £10. But for that arrangement he scarcely thought Dundee would be so cheaply served as at present. While in other towns competition might be adopted to secure the same advantage, he did not think a municipality should engage in the competition, but that it should be done by a private company.

By the Chairman: The competition was started in Dundee by the local company because the National Company would not lessen its rates, but since the amalgamation the Company had, of their own accord, gone below the £10 agreed upon, and now charged only £8. 10s.

Mr. JAS. CROMBIE, a merchant and shipowner of Aberdeen, who had been a subscriber to the National Company since its commencement, said he thought the system in Aberdeen was a very good one, and that temporary difficulties were promptly attended to and redressed. The Company had had difficulties with the Corporation with regard to way-leaves. He used the telephone in connection with his business eight miles outside Aberdeen, and since the twin-wire system had been introduced there had been a vast improvement in the service. The charge in Aberdeen was formerly £15, but it had been brought down to £10 by threatened competition. He considered that a competing system in the same area would lead to absolute confusion. He would rather pay a moderate charge for a good service than a less charge for a competitive service. He disagreed altogether with the evidence which Treasurer Blissett had given to the Committee in favour of municipal licences, and was certain that the people of Aberdeen would agree with him rather than with Mr. Blissett.

The Committee then adjourned until to-day (Friday).

LIGHT RAILWAYS BILL.

On Thursday, last week, the President of the Board of Trade moved for leave to bring in the long-promised Bill to facilitate the construction of Light Railways in Great Britain. The following is an abstract of *The Times* report:—

Mr. BRYCE said that frequently in past Sessions, and also in this Session, the House had had its attention called to the absence of facilities for the conveyance of agricultural produce from the agricultural districts to the markets of the country. He did not say that the measure would go very far in relieving the depression in agriculture, which was due to causes operating over the whole world, and many of which were quite irremovable by Parliament. He made no such claim, and he produced the measure as nothing more than a palliative of some evils. After reciting the events which had led up to the introduction of the Bill, Mr. Bryce said he would shortly state what were the provisions of the Bill, the provisions of which were, he said, based upon the recommendations of the Committee. Those recommendations went mainly to two points—namely, the cheapening of Parliamentary procedure and the relaxing of the requirements which it had been the custom of the Board of Trade to impose, in some cases under the absolute direction of Parliament, and in other cases under a sense of duty which had become practically imperative as regarded both the construction and the working of railways. As to procedure, the Bill proposed to commit the authorisation of light railways to County Councils, including in that designation county boroughs. If a County Council considered that a *prima facie* case was made out, then it was to appoint a Committee to inquire into the matter. The promoters were to make out their case, to state the area through which they would pass, and to show that they had consulted all the Local Authorities; thereupon the Committee was to prepare a draft Order, and that was to be sent to the Board of Trade, which was to consider it with a view to three points in particular. The first was the magnitude of the undertaking, so as to secure that under these exceptional provisions no railway should be carried out which ought to be subject to the judgment of Parliament. Secondly, the Board of Trade would consider the proposals from the point of view of the safety of the public. Thirdly, the Board of Trade would be charged with the duty of protecting landowners, and any landowner who thought that his land ought not to be taken compulsorily would have *locus standi* before the Board of Trade, in asking that the Order for the taking of his land should be varied. In making these proposals the Government was, of course, asking Parliament to part with a certain measure of its power; but he submitted that the time had come when in a matter of this kind Parliament might endeavour to effect the enormous saving which would unquestionably be the result of these provisions. As to the question of construction, with regard to these small lines the Board of Trade might be a little more tolerant of level crossings, might dispense with the present elaborate station arrangements, and in many ways might materially diminish the whole cost of construction and working, if only the necessary authorisation from Parliament were given. It had been stated that the Board of Trade was too severe. The department had felt bound to consider the safety of the public as its first charge until Parliament, as the organ of public opinion, authorised it to relax its requirements. But the evidence supplied had convinced the Board of Trade and the Committee that it was possible to dispense with a great many of those requirements in this case without any increased danger to the public or to the traffic. The same remarks applied also to the working of the lines. It had been suggested that public aid should be given to these enterprises from the national exchequer. He did not think the Government would be justified, in the present condition of the public revenue and of public opinion in regard to this question, in proposing a measure so novel and open to so many serious objections of policy. It had never been the policy of this country to subsidise railways, and Parliament would be making a serious new departure in taking such a step. The result of that policy in various foreign countries was well known. It had also been suggested that the making of these railways ought to be aided out of the local rates, and three members of the Committee signed a separate report in which they made that suggestion. There was, no doubt, much to be said for this suggestion; and he did not suppose that the Local Authorities, seeing how strong an interest they had in avoiding any unnecessary expense, would be imprudent in using the power if it were conferred on them. But, at the same time, he must feel that very great objections would be taken in the House to the conferring of such a power. Expressions of opinion had reached him from many quarters which made him feel that if the Government proposed to give to the County Councils the power of subsidising these undertakings, some persons would fear that they would remain ultimately as a charge on the rates, and the measure would meet with a great deal of opposition from which he hoped it would escape. They were, to a certain extent, in a stage of experiment. It might turn out ultimately that the making of these lines would be so great and clear a public benefit that either the national Exchequer or Local Authorities might be authorised to give them some aid or assistance. All he could say now was that the case did not seem to justify the trial of that experiment at present. Apart from what might be done by private enterprise, the formation of companies, and the public spirit of landowners, who, he believed, would in many cases feel that so great a benefit would be conferred upon their districts and properties by the construction of these lines that they would give the land necessary at a very low price, or perhaps for nothing at all—even apart from that, he believed it would be worth the while of many of the great railway companies to construct these lines.

Mr. CHAPLIN said agricultural depression undoubtedly existed in Ireland, but it was nothing like so severe, as he had reason to believe, as it was in numerous parts of Great Britain at the present time. Although State aid in the construction of light railways had been given in Ireland, the President of the Board of Trade said it would be too novel a precedent altogether and one which the Government could not possibly adopt. One thing, however, he was glad to hear, and that was that there was no possibility of any cost in connection with the light railways falling on the rates. The condition of agriculture was so bad at the present time that agriculturists could not bear the slightest addition to the burdens which already fell upon them.

Col. KENYON-SLANEY observed that this measure did not fulfil the idea of hon. members representing agricultural constituencies of every possible step that could be taken to relieve distress, and it would be regarded as a poor and paltry measure indeed. The Government were depending on a broken reed. They were depending on the generosity of a class of the population from whom they had taken away the power to be generous. They were depending on the business like capabilities of another class whose interests would go in the very opposite direction to that in which they hoped to enlist them.

Mr. STRACHEY submitted that those who represented English constituencies had a right to claim that so long as public money was given for the purpose of benefiting agriculture in Ireland and in Scotland the same policy should be pursued as regards England.

Capt. BETHELL said that it was possible that these lines of light railways might be of some use in certain parts of the country, but he doubted whether the power to make them would be generally put into force.

Mr. CROSFIELD had recently visited Holland, and he had come to the conclusion that the extreme prosperity of that country was due to its network of steam tramways.

Mr. TOMLINSON suggested that where there were tramways running along the roads the Board of Trade might require the proprietors to give certain facilities for bringing down agricultural produce as well as passengers. He did not believe that the agricultural districts could carry out a system of light railways or tramways without aid from the Government.

Mr. J. A. PEASE said that the case of Ireland was not a precedent. The position of Ireland was different from the condition of affairs which existed in agricultural districts at the present time here. When it was considered necessary to apply to the Exchequer for aid to make railways in Ireland it was to save thousands of the Irish people from starvation in the congested districts. The Government had, therefore, done well to refuse any national funds for the purpose of the Bill in this country. Distress and depression existed in other industries besides that of agriculture, and, if agriculture received this aid, in all probability other industries would claim it likewise.

Mr. T. H. BOLTON said it seemed to him that it was a Bill that would do no very great harm, and certainly it would do very little good.

Sir M. HICKS-BEACH said the principles of the Bill were good and useful; but he feared that the measure would not have the effect which they all desired. He thought that the financial question was at the bottom of the whole subject. Landowners had made these railways largely in the past. They had made branches at great cost to themselves, which the railway companies had starved, and had afterwards purchased at half the original cost. That did not hold out any hope that the railway companies would go to the expense of constructing these railways themselves. The landowners could not afford, in the present condition of agriculture, to do it. They had been penalised by the legislation of last year; they had suffered

Digitized by Google

from the general depression; and it was impossible, under present circumstances, for the English landowners to do what they had done in the past. They were driven to the conclusion that though, in some more favoured districts, the making of light railways might be promoted by the legislation now proposed, yet, where they were most wanted, and where agriculture was most depressed, this Bill would not secure their construction. He was very sorry that the Government had put their foot down against any policy of assistance by the State. He entirely differed from the view that the assistance given in Ireland was to save hundreds of thousands of people from starvation. The assistance was not given for that reason at all. In some districts where it was given in Ireland no question of starvation arose. The light railways were given to Ireland to relieve the general agricultural depression in that country, and what was good for Ireland in this respect ought, if wanted, to be good for England too. In saying what he had said he did not, however, forget the dangers of extravagance and jobbery in such matters. The Irish example had taught them a good deal in this matter. He should be glad to aid its passing; but he hoped that from that night forward they would hear no more about the Bill as a remedy for agricultural depression.

Leave was given to bring in the Bill, and it was brought up by the President of the Board of Trade and read a first time.

CORRESPONDENCE.

THE EWING HYSTERESIS TESTER.

TO THE EDITOR OF THE ELECTRICIAN.

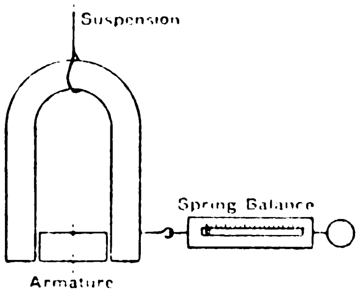
Sir: To the inexperienced student who begins to try experiments, it often seems as if all the actions of Nature were in conflict, and nothing succeeded; it is occasionally the case that the patient student is rewarded by unexpected facilities, and when there is genius to combine them, results are attained by simple means which previously could only be arrived at by complicated processes, and very stably too, that is, without the accuracy of these results being liable to be upset by minute variations in some of the conditions. This seems to be so in the case of the beautiful instrument Prof. Ewing has created—to rank it as an invention seems hardly just. By putting it in a practical form, whatever may be his pecuniary reward, he has made not only the electrical world, but the whole world, his debtor. For if I am not mistaken, the use of this instrument will so aid and forward the development of alternating current and phase plant, that we shall before long be attaining results of great commercial importance which are not within the reach of continuous currents. It has been the want of an instrument of this kind, which could be easily and quickly applied by iron and electrical manufacturers, which has caused much of the uncertainty regarding alternating current results, which has only slowly been lessened by the laborious tests which have hitherto been the only ones available.

My object in writing is not, however, so much to add to the chorus of eulogy with which Prof. Ewing's instrument was greeted, as to mention some experiments of my own, which do something towards confirming the result which Prof. Ewing himself says was unexpected, viz., that the readings of the instrument were little affected by comparatively considerable variations in the number of sample sheets used, that is, in the cross-section of the iron tested.

Supposing we take the armature of an ordinary continuous-current dynamo and place it symmetrically between the poles, there will be no resultant attraction. But, supposing the poles to be vertical, the attraction will be increased towards the top, if the armature is raised owing to the shortening of the two air-gaps at the top, and the lengthening of these at the bottom. The converse will be the case if the armature is lowered.

What, however, will happen if the axis of the armature is kept in the same plane, but the armature is moved horizontally to one side or the other? Except for a slight difference in the leakage lines, the reluctance of the magnetic circuit will not be altered, and the difference in the relative attraction of the two poles on the armature should be slight. Finding nothing on the subject in any of the books, I wrote to Prof. Silvanus Thompson, with a statement of the problem, on January 13th last, and he agreed that it had not hitherto been definitely solved.

In writing, I mentioned the following experiment bearing on the question. A U-shaped horse-shoe steel magnet, 5in. high, 1¾in. between the poles, the steel section being ¾in. by ⅝in., or, say, ½ square inch, was suspended with the poles downwards, and to one leg a small spring balance was attached. Under ordinary circumstances the magnet lifts 4lb. easily; 45 strips of armature iron, 30mm. thick and ¾in. broad and 1½in. long, were next cut, and piled up in a heap 1½in. high, the whole being tightly tied together. The bundle was now fixed between the poles of the magnet, with the laminations horizontal and touching one side, thus leaving



¼in. air-gap between the ends of the sheets and the other pole. A series of trials showed that a pull of 4oz. only was needed to detach the magnet from the armature. The 45 sheets were now removed, and one sheet only substituted for them. That is, the section of the armature was reduced to $\frac{1}{45}$th. Under these conditions the pull required to detach the pole from the single sheet was 8oz. to 10oz., or double what it was before with 45 sheets.

Although on consideration one sees why it should be so, I must confess this result was unexpected at the moment. The actions involved, however, seem analogous to those of which Prof. Ewing has availed himself with such success. In his case the greater coercive force with the fewer sheets increases the hysteresis as the section of the iron is diminished, and so secures a balance over a certain range.

As regards the use of straight samples *versus* discs. I am quite confident that Prof. Ewing's method is by far the most advantageous for manufacturers, as, owing to the fact that great exactness in the action of the samples is not of great importance, the samples can be cut with a pair of shears from sheets when sampling them. This would be far less trouble than taking the sheets to a press, and the small slip taken from the edge makes much less waste than if a circle is taken out. More sheets can therefore be sampled in a given time for less waste if straight pieces are used, and this, as Prof. Ewing has stated, is of far greater importance to dynamo and transformer builders than very exact results with a few sheets. If draughts are found to affect the readings, it would be very easy to shield this part of the instrument with a xylonite screen passing through the air-gaps.—Yours, &c.,

April 24, 1895. G. L. Addenbrooke.

EXPERIMENTS ON THE SHAPES OF RAIL GROOVES FOR TRAMWAY CURVES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your issue of the 26th there appears a Note, quoted from the *Engineer*, on "Grooved Rails for Electric Railways." The experimental research there described is very interesting, but unfortunately no results are given, and although the shape of groove obtained might be predicted by those who have really studied the subject, yet it would be valuable to have the result depicted in graphic form. Cannot photographs of the impression be published?

From the heading of the Note it might be supposed that an electrically-driven car required rails differing from those used when the wheels are driven by other mechanical power; this, of course, is not so. The employment of electricity has, however, brought a fresh class of mind to bear upon this as well as upon numerous other subjects, and it is satisfactory to see that further attention is being given to so important a detail.

Digitized by Google

In the experiment described, the result would have been just the same if, instead of turning the leading axle, the frame had been pulled or pushed forward, because the frame carrying the wheels was rigidly attached to the stiff radial board, and it is doubtful if the groove produced will correctly indicate what would occur in practice. It would be well to repeat the experiment, pivoting the frame to the radial bar, not in the centre, but over the leading axle. What would then happen might also be predicted, and would approximate more nearly to theoretical requirements, but would give a result somewhat difficult for practical construction.

In dealing with curves the difficulty arises chiefly in entering and leaving them. The omission to realise this has led to many mechanical devices for radial axles, &c., that have not proved satisfactory in practice. The experiments to be really valuable should show the action of the flanges of the car wheels upon the rails when entering and leaving a curve, and also when changing from right to left on a double curve.

It is to be hoped that the investigation will be continued, and the result published.—Yours, &c.,

April 30, 1895. M. Holroyd Smith.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NOW READY.

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Although about 100 pages are added to the book, no addition is made to the price, which is 7s. 6d., post free 8s. 3d., abroad 9s.

NEW BOOKS AND EDITIONS.

The following New Books and Editions of "The Electrician" Series *can be obtained of the Booksellers or direct from the Publishing Offices:—*

Laboratory Notes and Forms.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. A full prospectus can be obtained post free.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

A Large-Sheet Table, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 3s. 6d.; Unvarnished, 2s.—each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

"Electric Motive Power."—A new work, by Mr. Albion T. Snell, with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains some 230 illustrations, a large proportion of which have been specially made for the book. The price is 10s. 6d. post free (abroad 11s.).

"The Art of Electrolytic Separation of Metals."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

"Electro-Chemistry."—This useful work, by Dr. G. Gore, is still on sale, the price being 2s., post free.

"The Work of Hertz."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. net., is now ready.

"The Electrician."—A special notice concerning certain changes in the price, &c., of this journal (commencing with the new volume this day) will be found on page 10.

Tenders Invited.—The Brighton Corporation invite tenders for the supply and erection of boilers at the Corporation Electricity Works, North-road. The Corporation also invite tenders for the supply of india-rubber lead-covered armoured cables. Specifications and particulars may be obtained at the office of the town clerk, Mr. F. J. Tillstone, and tenders, addressed to him, must be in by May 13th.

Tenders Invited.—The Brighton Corporation also invite tenders for the supply and erection of arc lamps, switches, &c. Specifications and particulars may be obtained of the town clerk, Mr. F. J. Tillstone, and tenders, addressed to him, must be in by May 27th.

——— The Corporation of Birkenhead invite tenders for the supply and erection of apparatus and plant for their electric supply works. Some further particulars will be found in our advertisement columns. The requirements include boilers, engines, dynamos, a battery of storage cells, instruments, cables, street boxes, &c. Plans will be ready after the 8th inst., and all further information can be obtained at the office of Mr. Alfred Gill, town clerk, Town Hall, Birkenhead; or at the office of Mr. J. N. Shoolbred, C.E., 47, Victoria-street, London, S.W. The contract is in five sections, which can be tendered for separately. Tenders must be in by 12 noon of the 23rd inst.

——— The Vestry of Shoreditch (London, E.C.) invite tenders for the erection of a dust destructor, furnaces, boilers, &c., capable of dealing with 20,000 tons of refuse per annum, and of producing the quantity of steam specified in the conditions required for electric lighting and other purposes. Specification and sketch-plan and other information can be obtained from Messrs. Kincaid, Waller and Manville, the engineers to the Vestry, 29, Great George-street, Westminster, S.W., and tenders must be sent in to Mr. H. Mansfield Robinson, solicitor and Vestry clerk, by 4 p.m. on Monday, May 20th.

——— The Corporation of Tunbridge Wells require tenders for the wiring of the municipal buildings. Tenders by the 28th instant.

——— The Manchester Corporation invite tenders for the supply, delivery and erection of electric lighting machinery required for the lighting of the new Foreign Animals Wharf, at Mode Wheel. Tenders have to be in by 9 a.m. of the 13th inst.

——— The Derby Town Council have accepted the tender of Mr. E. Danks, Oldbury, for three mild steel boilers for the electricity works, at the sum of £1,570.

Tenders Accepted.—The Electric Lighting Committee of the Hull Corporation have accepted the tender of Messrs. Amos and Smith, for the new boilers at the electric lighting works for the sum of £574, and the tender of the same firm for steam pipes for £146. Messrs. J. G. Statter and Co.'s tender for instruments has been accepted for the sum of £78. 10s., Messrs. Crompton and Co. being next lowest at £98, and the amount of the tender of Messrs. Siemens Bros. and Co. was £115.

——— The Birkenhead Town Council have accepted the tender of Messrs. Holme and Greene, of Liverpool, for the erection of the new chimney at the proposed central electricity station for £850.

Personal.—Mr. S. Crichton Hannah, who has been with Messrs. B. Verity and Sons for over 20 years as designer, has taken premises at 5, John-street, Adelphi, London, W.C., and is prepared to supply designs and working drawings for electric fittings, &c., for the trade.

Agency.—Messrs. J. C. Lyell and Co., of 55, Victoria-street, London, S.W., have been appointed sole agents for London, Birmingham, and the South of England, for the Svea incandescent lamps manufactured by the De Laval Glöd Lamp Company, of Stockholm. The agents for Manchester are Messrs. George Thomas and Co., of 72a, Deansgate; for Glasgow, Mr. Hugh Loudon, 12, Dixon-street, and for Belfast Mr. John Hind, jun.

Award.—Messrs. Crossley Brothers (Limited), of Openshaw, Manchester, have received a cable from their Australian agents announcing the receipt of the first award for their well-known oil engines at the Hobart Town Exhibition, Tasmania.

Dividends.—A dividend of 10s. in the £ is payable in the separate estate of Octavius Buss (of Young and Buss, electric bell makers), at the office of Mr. H. W. Figg, 37, Upper Thames-street, London, E.C., on any Wednesday or Thursday, after May 1st.

Dissolution of Partnership.—The partnership between A. B. Gregson and G. E. Newboult, trading at 12, Swaine-street, Bradford, as electricians and engineers, under the style of Gregson and Newboult, has been dissolved. Debts will be paid by A. B. Gregson, who continues the business.

Liquidations.—Mr. T. D. Pillans, 11, Sheen-park, Richmond, Surrey, has been appointed liquidator in the voluntary winding-up of the European Sims-Edison Electrical Torpedo Company (Limited).

——— A meeting is to be held at 107, Cannon-street, London, E.C., on May 27th, at 5:30 p.m., to receive an account of the winding-up of J. R. Powditch and Co. (Limited), electrical engineers and contractors.

——— Under the winding-up order recently made against Martiny (Limited), meetings of creditors and shareholders were held on Wednesday last; but as a quorum could not be formed, the meetings were adjourned. No statement of affairs has yet been filed.

Digitized by Google

BANKRUPTCIES.—A summary of the statement of affairs in the bankruptcy of W. J. Kelly has been issued, which shows liabilities £2,751. 13s. 5d., assets nil. The debtor states that, having for 14 months prior to July, 1892, been secretary of Poole and White (Limited), he was in that month appointed receiver of the Company's business at the instance of Second Debenture holders, but that in February last he was superseded by a receiver appointed on behalf of the First Debenture holders. With the exception of £2. 17s. 6d., he denies personal liability for any of the debts scheduled in the statement. The public examination of the bankrupt takes place this day (Friday), at 11 o'clock a.m., at Bankruptcy-buildings, Carey-street, W.C. The following is the list of principal creditors :—

Abel and Imray	£11	7	0
Edison and Swan United Electric Light Company	457	16	0
The Electrician	82	15	9
Electrical Review	68	8	0
General Electric Company	171	7	2
L. Hervé	109	10	5
International Electric Company	47	1	2
F. Kusterer	34	7	1
Minton, Hollings and Co.	25	0	0
Nalder and Harrison Construction Syndicate	21	14	6
R. Orwin	57	12	8
T. Sanders, Birmingham	66	13	0
Taylor, Tunnicliff and Co., Hanley	48	0	4
Binney and Co., Ilford	27	11	10
Gaskell and Grocott, Longport	549	19	2
W. T. Glover and Co., Manchester	157	0	0
Mills, Walker and Co., Stourbridge	36	1	3
Orme, Evans and Co., Wolverhampton	52	16	1
Golding and Sharpe	548	15	0

Rest of London.

——— At the meeting of creditors of E. H. Berry, trading as Berry and Pope, electrical engineers, Burnley, Lancs., Mr. H. Lloyd Price, 79, Mosley-street, Manchester, was appointed trustee, with a committee of inspection.

——— The first statutory meeting of creditors in the failure of J. Torr Todman was held before Mr. A. H. Wildy, official receiver, on Tuesday. No accounts had been filed, but the debts were stated to amount to £700. No proposal was before the meeting, but it was intimated that an offer of 7s. 6d. in the £ would be brought forward, and the meeting was adjourned for three weeks to allow the debtor to formally submit the offer to his creditors.

VAL D'AOSTA ELECTRO-METALLURGICAL WORKS AND MINES.—We hear that the syndicate who own these important works in Italy have decided to offer them for sale by public auction at the London Auction Mart. The works premises cover some 12 acres, and are equipped with 300-H.P. turbines, dynamos, and other plant. With skilled labour at 2fr. per day, water power at £10 per 100 H.P. per annum, a paternal Government which protects its manufacturers by import duties, and other advantages—of climate, &c., it is probable that a spirited competition will take place at the sale, which is expected to take place during the current month.

"D. P." ACCUMULATORS.—As our readers are aware, up to the present time this accumulator has been exploited by Messrs. Drake and Gorham, of 66, Victoria-street, S.W., who some years back appointed Messrs. Johnson and Phillips as sole manufacturers for the United Kingdom. Owing to the success which the battery has attained it has now been decided to form a separate company, who take over the whole of the battery business from May 1st. This Company is styled the D. P. Battery Company, and the London branch has been established at 66, Victoria-street, S.W., where all inquiries should be addressed. The works are for the present at Old Charlton, Kent. The new Company will retain the services of Messrs. Drake and Gorham, who have both in the past been connected with the E.P.S. Company and with the Elwell-Parker battery, so that these gentlemen bring an exceptional experience in battery work to the service of the new concern. Mr. Claude Johnson, of Messrs. Johnson and Phillips, has undertaken the management of the works at Charlton, where considerable additions to the existing plant are under consideration. The business in the battery has already assumed large proportions, and doubtless this consolidation of interests will obviate any possible jealousy on the part of the trade, and should lead to further demands for an accumulator which, since its first public appearance at the St. Pancras Vestry Exhibition in 1891, has gradually won its way with the trade, and proved itself worthy of a good share of patronage from battery users throughout the kingdom.

SCHUCKERT AND CO. (NUREMBURG).—This firm has issued an album containing particulars and illustrations of the central stations erected by the firm from 1887 to date. Most of these stations are for low-tension continuous currents, and work with the slow-speed dynamos coupled direct to marine type engines, so generally adopted in Germany. Hamburg, Hanover, Altona, Christiania, Aix-la-Chapelle. The distribution is throughout on the three-wire system. There are about 35 stations in all, whose output ranges from 3,750 kilowatts to 50 kilowatts.

THE EDISON SCREW LAMP SOCKET PATENT.—In reference to a Note which appeared in our last issue, Mr. Gover, secretary of the Edison-Swan Company, writes :—"The paragraph in to-day's *Electrician*, stating that 'to-day expires the Edison Screw Lamp Socket Patent No. 1802 of 1881,' I suppose is intended to mean that the period of 14 years for which the patent was granted ends to-day. As a matter of fact, this patent came to an end in 1885, no renewal fees having been paid upon it, showing that it was not considered to be a patent of importance, as your present paragraph might lead some people to suppose."

EPSTEIN BATTERIES.—We learn that the Notting Hill Electric Lighting Company have placed an order with the Epstein Electrical Accumulator Company for two new batteries of large capacity, to be put in at their supply station, Bulmer-place, Notting Hill Gate, London, W.

ELECTRIC COOKING AND HEATING APPARATUS.—The Electrical Company (Limited), 122 and 124, Charing Cross-road, London, W.C., send their latest catalogue of cooking and heating apparatus, comprising hot plates, plate warmers, boilers, fitted with either the discs or rings, pans and the saucepans, frying pans, tea and coffee cans, grills, flat irons, cooking stoves, and a toy kitchener, &c. The catalogue is fully illustrated, the concluding plate showing a *fin-de-siècle* kitchen at the Chicago Exhibition.

NEW EDITION.—A new and enlarged edition of Mr. W. Perren Maycock's "First Book of Electricity and Magnetism" will shortly be published by Messrs. Whittaker and Co.

ACTON.—A short time back it was agreed by the District Council to transfer their provisional electric lighting Order to Messrs. New and Mayne on condition that certain stipulations as to a sliding scale, &c., were agreed to by that firm. At the last meeting of the Council Messrs. New and Mayne's acceptance of the conditions was notified. Upon this a discussion ensued on a motion by Mr. Buxton "That the sale of the Provisional Order should be rescinded." After much discussion an amendment, "That the transfer of the Order should be postponed until the opinion of the parochial electors had been ascertained" was agreed to.

ADELAIDE (SOUTH AUSTRALIA).—The question of lighting this city by electricity is being actively discussed, and Messrs. R. W. Thomson and Co., of Leigh-street, have submitted tenders for lighting portions of the city. By last reports the Mayor has been requested to call a meeting of ratepayers to consider the whole question, and to submit full details of such schemes or proposals as have been already discussed by the Corporation.

BEDFORD.—The Electric Lighting Committee have presented a report preliminary to that which is to be published in July next. From the summary it would appear that the amount paid to date on account of the electricity works is £10,644. 2s. 8d., and the amount owing £2,138. 14s. 10d. The original sum borrowed (£12,000) has, therefore, been exceeded by about £800. The Committee report that they have every reason to be satisfied with the way in which the work has been done by the various contractors, including Messrs. Johnson and Phillips (machinery), the Telegraph Manufacturing Company (mains, &c.), Messrs Grafton and Co. (travelling crane), Mr. T. H. Coleman (building and shaft), and Mr. F. H. Medhurst (consulting work), and that the installation has been most successfully carried on by the staff at the works, under the superintendence of Mr. W. Hope-Johnstone, the engineer, who has sole charge of the works. The light has given general satisfaction, as is evidenced by the increasing demand. The supply of current from December 5, 1894, to March 31st last will recoup the Council for all working expenses and materials supplied during this period, and provide a small balance, which the Committee consider a satisfactory result. The Committee submitted estimates prepared by the engineer for extending the lighting area, and recommended that application be made to the Local Government Board for borrowing the amount required to carry out the complete scheme. About £13,000 has already been expended, and a further £26,764 would be required. Mr. Richards (the Chairman of the Committee), replying on the discussion which followed, said that when St. Pancras started its electric lighting there was no Vestry so much abused, but it was a grand example to work up to. He felt that the Bedford Council's electric lighting undertaking was bound to grow into a brilliant success. The proposal to obtain borrowing powers on £26,000 was unanimously agreed to. A proposal from the captain of the fire brigade that electric fire alarms should be placed in the principal streets was referred back for further consideration.

BELFAST.—The Electric Light Committee of the Corporation considered at their last meeting the question of supplying electric current for heating and power purposes during day hours on a reduced scale of charges, and it decided that current for these purposes be supplied at 4d. per unit, with discounts. The charge for lighting is 7d. per unit.

Digitized by Google

Birkenhead.—In its report for the year the Finance Committee of the Town Council asked for a sum of £1,500 for the purpose of lighting the Town Hall by electricity. The Committee recommend that the light should be permanently installed, "as the rooms of the Town Hall are used for high-class entertainments, and are universally admitted to be much cooler and pleasanter when lighted by electricity than when lighted by gas. This form of illumination is recommended as better for the health of the Corporation officials," and the work of installation has to be completed by September. After discussion the suggestion of the Committee was modified, and £750 voted for electric lighting. Mr. Alderman Deakin stated at the last meeting of the Town Council that Mr. Shoolbred's plans and specifications for their electric lighting scheme had already been placed before the Imperial authorities, and he hoped, if advertisements for tenders in connection with the work were approved by the Council, that he would be able to have the generating station ready for the supply of current for the coming winter. At its meeting on Wednesday, the advertisements for tenders were approved, and yppear in another column of this issue.

Birmingham.—It will be remembered that a few weeks back a heated discussion took place as to the allocation of the tenders for supplying electric plant and apparatus for lighting, power, and teaching purposes at the Municipal Technical School. The contract was finally given to Messrs. D. and G. Graham, of Glasgow. As the members of this firm have now applied for the sequestration of their estates, the whole matter of these tenders will probably have to be again considered by the City Council. The total amount of the contract given to Messrs. Graham was £6,080. 14s. 2d.

Burglary.—The recent burglary on the premises of the Brush Electrical Engineering Company in Queen Victoria-street, London, was perpetrated by a clerk named Eve, who succeeded in forcing a cash-box and stealing therefrom £207. 10s. The prisoner, when caught at Aberdeen, had succeeded in disposing of nearly the whole of the money. He had previously served eight months' hard labour for forgery, and was committed for trial.

Bury St. Edmunds.—We are notified that a syndicate has been formed for the purpose of supplying business premises in the neighbourhood of Abbeygate-street with electric current. Messrs. W. J. Crampton and Co., of Cambridge and Great Yarmouth, have been entrusted with the necessary installation work.

Derby.—At the last meeting of the Town Council the Electric Lighting Committee obtained permission to apply to the Local Government Board for sanction to borrow £5,000 for electric lighting purposes. Alderman Leech said the undertaking was in a prosperous condition, and he expected to be shortly in a position to present a satisfactory balance sheet.

Ealing.—Messrs. Bramwell and Harris, having accepted the terms offered by the District Council, have been duly appointed consulting engineers to the electric lighting works.

Edinburgh.—The Electric Lighting Committee of the Town Council has considered several requests for the extension of the electric lighting to thoroughfares not already mained, and has granted the applications. A request from Surgeons' Hall for private lighting is to be inquired into, and a report presented.

The Falls of Foyers.—At the meeting of the Inverness County Road Board on Wednesday a motion was carried that the proposal of the British Aluminium Company, relative to the submersion of certain roads in Stratherrick, and the alteration of other roads in connection with the proposed diversion of the Falls of Foyers, was approved on the condition that the company maintain the road for two years. The matter was to come before the County Council for final decision yesterday (Thursday).

Fife.—At a meeting of the County Road Board on Tuesday, the Sub-Committee's report on telephones was submitted, and it was agreed to give powers to the Committee to make a fair and reasonable agreement with the Telephone Company on the basis of 2s. 6d. per mile of wire for way-leave and as much accommodation as possible from the Company in the way of free telephone instruments at several of the police offices in the county.

Fulham.—The Vestry at their last meeting decided to appoint a special committee to consider and report as to the advisability of applying for a Provisional Order to supply electric light in the district, and also as to the construction of a refuse destructor in connection with the scheme.

Hampstead.—In reference to the proposal made by the London and Hampstead Battery Company, suggesting a scheme for dividing the work of electric lighting in this parish between the Company and the Vestry, the latter body have decided not to entertain the proposal, as they do not consider it advantageous either to the Vestry or to the parish. The question of the Company's rights in the matter is under consideration by the Lighting Committee. The Committee have given Messrs. W. T. Glover and Co. an order for the necessary cables, jointing boxes, &c., required for the extensions recently sanctioned by the Vestry.

Hanley.—At a special meeting of the Town Council on Tuesday the minutes of the Electric Lighting Sub-Committee were considered. A plan of the proposed extension of the electricity works had been submitted by the borough engineer and the electrical engineer to the Corporation (Mr. G. H. Cottam). It was stated that the demand for current in the centre of the town would necessitate the putting down of a new high-tension cable of double the existing capacity between the works and the Town Hall, estimated to cost £5,508. The extension of the generating station and mains would necessitate an expenditure of £5,900, making, with other items, a total estimate for the extensions of £19,000, and an extra sum of £1,000 was added for contingencies. The total expenditure for the scheme to date is £47,000. The Committee recommended that application be made to the Local Government Board for sanction to borrow a further sum of £20,000, repayable in 25 years. The minutes were unanimously confirmed, and several members expressed their satisfaction at the success of the municipal electric lighting undertaking.

Huddersfield.—The official accounts of the electric lighting department of the Huddersfield Corporation to December 31st last are just issued. The total amount borrowed to date at 3½ per cent. interest is, for building (repayable in 30 years) £10,800, and for general purposes (repayable in 15 years) £33,200, leaving the department with further borrowing powers to the extent of £6,000. The capital account shows a total expenditure of £46,041. 9s. 4d. The sale of current for the year realised £3,214. 8s. 4d., including £173. 15s. for public lighting. Receipts from meter rents amounted to £232. 8s. 2d., and by sale and repairs of lamps and apparatus £133. 12s. 1d., making a total of £3,580. 8s. 7d. The total expenditure for the year has been £2,184. 5s. 5d., leaving £1,376. 3s. 2d. to be carried to the net revenue account, and £20 as provision for bad and doubtful debts. The total deficiency to December 31, 1894, is £2,065. 4s. 9d., against a deficiency of £2,547. 7s. 9d. at December 31, 1893. The total number of units generated during the past year was 265,146, of which 156,169 were sold, 9,487 were used at the works, and 99,490 are unaccounted for.

Hull.—Col. C. H. Luard, R.E , Local Government Board Inspector, recently held an official inquiry into an application by the Corporation for sanction to borrow £2,800 for electric lighting extensions.

Kingswood (Bristol).—An agreement has been sealed by the Urban District Council as to the terms upon which the local tramway company, which is adopting electric power on its lines, are to pay annually for the right to erect poles for their overhead wires.

Leicester.—Exception is taken by many writers to the loca Press to the action of the officials of the Corporation in soliciting orders for installation work. One firm of electrical engineers, in a communication to the *Leicester Post* of the 29th ult., points out that the gas department of the Corporation are making nearly £27,000 profit per annum, and urge that touting for installation orders is, at least under these circumstances, inadmissible and undignified, and calculated to do great injury to local firms engaged in the supply of fittings and apparatus for electric lighting. Perhaps the most serious point is the complaint that the Corporation officials, in their anxiety to obtain business, claim that their workmanship is superior to that of private firms. The difficulty of obtaining business where official competition has to be overcome is notoriously great; but if, in addition to the perhaps not unreasonable preference of the citizens to entrust their work to the Local Authorities, the element of misstatement is introduced, the lot of the local tradesmen will, indeed, be a hard one. So far as Leicester is concerned, the regulations and tests imposed by the authorities, which are described as exceptionally severe, are safeguards against common goods or bad workmanship. The letter referred to concludes:—

"The papers containing the report of the opening of the new electric light station this week state that the profit made on the fixing department is going towards the loss on the present supply of current. Sir, we contend this is not fair. If the Corporation are going in the future to reap the benefit of profit by supplying the current for the light, we consider they ought to bear the loss now, and not try and cover it by obtaining the work from electrical engineers in the town. The loss they are now making on supplying the current, or the gain they will make in the fitting department in the future, will certainly not make any appreciable difference in the rates, but the electrical trade would feel the benefit if they had all the fixing to do. We are informed that the competition has not however, stopped at installations from the town mains, but they have now commenced supplying and fixing private electric light installations. We should like to know where the competition of Leicester Corporation with us will end. Do they intend to fix any electrical apparatus as telephones, &c.? It is most unfair that any one trade which promised to become fairly established here (manufacturing as well as fixing), should be singled out to compete with the rates they have to help to pay. It would be interesting to know where the capital for providing the stock and material for installations is obtained from; whether it is from the rates or from money granted for the supply station; also whether the interest on this amount and the time of the officers touting for electric light orders is deducted from the profits."

Digitized by Google

LIVERPOOL.—It is stated that the result of the inquiries, made by Sir Frederick Bramwell and Mr. Barrow, into the financial and general position of the Liverpool Electric Supply Company, have so far proved perfectly satisfactory. The work of inquiry is not yet completed, but it is expected that the report will be shortly issued to the Corporation, who will discuss the matter at an early meeting. The purchase is stated to be contingent on the extension of the city boundaries being carried out, as a portion of the Company's plant is situated both within and without the city's present boundaries.

MADRAS.—Recently the officials of the Madras Tramways Company made trial trips with the newly-equipped electric cars. The preliminary trips were very successful, but subsequently on two occasions a hitch occurred, each time at the same spot. A visit has been paid to the works by the Governor (Lord Wenlock), when Mr. O'Shaughnessy, the chief engineer to the Company, conducted the party over the power station, and Mr. Gadsby, the Company's electrician, showed the brilliant effect of the electric lighting installation carried out by the Company.

METROPOLITAN ASYLUMS BOARD.—A letter has been received from the Electrical Trades Union, asking that a clause may be inserted in contracts for electrical work given out by the Board insisting upon what is termed "trades union working regulations" being complied with. The matter was referred to the Committee on Contracts.

OLDHAM.—At the meeting of the Town Council, on Wednesday, the Electric Lighting Committee reported that Prof. Kennedy had estimated the cost of the electric lighting extensions at £10,000. The original estimate was £27,000, and of this sum £25,550 had already been expended. The applications for current had been so numerous that the Corporation's plant was not sufficient to meet the increased demand, and they were obliged to extend the cables to Werneth Park and along Huddersfield-road.

PERTH.—The Waterworks Committee have recommended the Commissioners to sanction the lighting of the works by electricity, and the suggestion has been adopted. It is estimated that, with an initial outlay of less than £100, a saving of about £30 per annum will be effected over the gas-lighting cost. When repairs have to be effected in the wells under the engines, it has been found necessary in the past to provide movable lights, and it is considered that the adoption of the electric light will obviate the use of movable lights, and enable the work to be carried out in a much more satisfactory and efficient manner.

PLYMOUTH.—This otherwise go-ahead town, which is not inaptly termed the metropolis of the West, appears singularly backward with regard to electric lighting. At a meeting of the Western District Ratepayers' Association last week, one of the members pointed out that wherever electric lighting had been introduced by the Local Authority it had proved financially satisfactory to the ratepayers, and as a result of the persuasive eloquence of this gentleman a committee was appointed to consider the subject with the object of waking up the Local Authorities to a sense of their remissness in this important matter.

PRESTON.—A suggestion made at the last meeting of the Town Council that advertisements should be issued for tenders for lighting the Town Hall and Public Hall by electricity was discussed, but no action was taken in the matter. It is probable that the Town Hall Committee will consider the subject at its next meeting.

ROTHESAY.—With regard to the lighting of the harbour at Rothesay by electricity, the Harbour Committee, at a special meeting of the Harbour Trust and Town Council, recommended that the scheme proposed by Mr. Mavor, of Glasgow, should be proceeded with. Although the feeling of the meeting was generally favourable, the gas interest was fully represented, and was ultimately successful in postponing the further consideration of the matter for the present.

SHIPBUILDING AND THE ELECTRIC LIGHT.—About 18 months ago the officials at Devonport received instructions to utilise the spare electric light plant in the Dockyard for lighting ships in course of construction on the building slips. This was done, and the experiment has been so satisfactory that the Admiralty have now decided to spend a large sum of money in perfecting the arrangement, and when completed none but the electric light will be used on a ship from the time she is laid down until she is passed into the Fleet Reserve. During the present year it is intended to spend at Devonport £2,650 on additional plant, one half of which will be for perfecting the electric lighting arrangements of ships in course of building, and the other half for additional lighting plant to be used after the vessels leave the building slips.

SHIP LIGHTING.—Very few of the vessels of the principal steamship lines now leave our shores without an electric lighting outfit. Messrs. J. H. Holmes and Co., of Newcastle-on-Tyne, have recently secured orders for electric lighting plants for a number of the vessels belonging to the Russian Steam Navigation Company, and for steamers now building for the Russian Volunteer Fleet. The firm are very busy with ship-lighting plants.

ST. HELENS (LANCS.).—The Gas and Lighting Committee, after considering the report of Mr. R. Hammond on the proposed electric lighting scheme, have decided to put in plant at the gas works in Warrington-road. It is intended to first supply current for lighting the Town Hall and the Gamble Institute, and to arrange the plant so that, should the demand warrant it, extensions may be made at any time. Mr. Hammond has been instructed to submit plans and specifications for the necessary site and plant.

A SHAM ELECTRICIAN.—Wolverhampton has recently been troubled with a young man named Waterhouse, who rented a shop in Birch-street at 2s. 6d. per week, where he represented himself to be carrying on the trade of an electrician, and claimed to have in stock dynamos and other electrical machinery and apparatus. The accused started business with a capital of £1. 13s. 7d., and succeeded in obtaining various sums of money from tradesmen in the district.

SHOREDITCH (LONDON, E C.).—At a meeting of the Vestry last week the Electric Lighting Committee recommended issuing an advertisement for a clerk of works at a salary of £3. 3s. per week, to superintend the erection of the buildings in connection with the Vestry's electric lighting scheme, and the recommendation was approved.

STORES LIGHTING.—The Ryhope (near Newcastle) Co-operative Stores were lighted electrically for the first time on the 20th ult. The installation has been carried out by Messrs. Barnett and Co., of Newcastle-on-Tyne, at a cost of £1,000; six arcs and 200 incandescents are used.

SYDNEY (N.S.W.).—In an exhaustive report presented by the City Surveyor (Mr. Richards), dealing with the treatment of the city refuse, he recommends the application of a purifying liquid, "electrozone," prepared from electrically-treated sea water, which he considers secures perfect decomposition and disinfection.

TUNBRIDGE WELLS.—Petitions are being received from various suburban and other centres, asking that the area of the original electric lighting scheme may be extended. Contracts having been entered into absorbing the whole of the money for which the Electric Lighting Committee have obtained borrowing powers, it has been found impossible to grant the request of the petitioners. Owing to the very large number of applications for electric current, the Committee are of opinion that the time has arrived when considerable extensions should be considered, and recommend the Town Council to apply to the Local Government Board for powers to borrow a further £12,000 for this purpose.

WORCESTER.—At a meeting last week of the City Council, Mr. Millington, the chairman of the Finance Committee, made an unofficial statement as to the probable receipts and expenditure of the first year's working of the Council's electric lighting scheme. For the previous six months to March 25th, he estimated a debit balance of £17, in addition to the sum required for interest and repayment of capital. For the whole twelve months they would have to provide £5,096, and their probable receipts would be about £5,250. The actual amount of capital expended up to April was £57,083. 6s. 1d., which left an unexpended balance of nearly £3,000 out of the £60,000 voted by the Council for electric lighting purposes. Against this balance there was a claim by the contractor for rather more than £1,000, regarding which the Council disputes its liability.

YORK.—A special meeting of the City Council on Monday discussed the report of the Streets and Building Committee, which recommended the adoption of the scheme of the Electric Construction Company for the electric lighting of the city, and further recommended the acceptance of the Company's tender to supply the necessary plant and fittings for the sum of £10,865, and to work the plant for a term of three years in consideration of the payment by the Corporation of the following charges per unit for electricity supplied:—3¾d. per unit on a minimum of 75,000 units per annum, and on quantities up to 150,000; 3½d. per unit on 150,000 to 300,000 units per annum; 2¾d. on over 300,000 units. A lengthy discussion ensued, and several amendments were proposed and argued, but in the end the following amendment was carried:—"That the report be referred back to the Committee, with an instruction to report further on the electric lighting question, and particularly as to (1), the entire cost of plant, buildings, and land in each case; (2), the various works visited by them; and (3), whether Prof. Kennedy agrees with the advice given to them by the City Engineer." Mr. Ald. Wragge said that it seemed to be the intention of certain members of the Council to defeat, if possible, the installation of the electric light in the city. This opposition was contrary to the wishes of the ratepayers, who were anxious that the electric light should be established. The large towns of Yorkshire were pushing ahead with their electric light installations, and they would soon find the ancient city of York alone without the modern illuminant, although there was no city where the electric light would be of more service than in their own.

LEGAL INTELLIGENCE.

Slade v. Hooper's Telegraph and India Rubber Works (Limited).

This was an action heard in the City of London Court, before Sir Forrest Fulton, Q.C., and a common jury, and brought by Messrs. Slade, Templeton and Co., engineers, of New Broad-street, E.C., to recover £114 for telegraph buoys and other goods supplied to the defendant Company. The defendants paid £47. 13s. 1d. into Court, and raised a set-off and counter-claim for the balance of £66. 6s. 11d. The defendants, it was stated, were the contractors for laying a telegraph cable in Cuba. and had ordered 12 buoys, which were needed for the purposes of that work, from the plaintiffs. The plaintiffs say that after the order was given, Mr. Gee, the Managing Director of the defendant Company, requested certain alterations to be made in the original specification, This caused delay in the manufacture of the buoys, but ultimately the work was completed, and the buoys shipped to Cuba. The defendants declined payment on the grounds that there had been undue delay, that they had been put to expense in consequence, and that the buoys were not made in accordance with the order. Their counter-claim of £55. 16s. 11d. was made up of expenses to which the defendants alleged they had been put in consequence of the defects and delay in delivery. The principal question at issue was whether there had been unreasonable delay in delivery. The plaintiffs admitted that time was to have been of the essence of the contract, but said that in consequence of the alterations made at the defendants' request there was delay, and that they were only bound to deliver within a reasonable time, which they had done. After the case had proceeded for some time, the learned Judge said it was not one which could be conveniently tried by a jury. He should, therefore, refer it to an arbitrator. A formal verdict was returned for the plaintiffs for £98, and for the defendant on the counter-claim, subject to a reference to Mr. F. S. Jackson, the Registrar.

Whiffen and Others v. the Crompton Electric Supply Company of Australia (Limited).

In an action in the High Court, it was asked that the secretary of the Company (Mr. F. R. Reeves) should be appointed as receiver and manager. There were three series of debentures issued, and plaintiffs were holders in all of them. The interest was in arrear, and this action was taken in order to protect the property and assets of the Company, the whole of which were in Australia. The secretary was resident in England, but plaintiffs were ready to undertake for his receipts.

The application was granted, but power was reserved on the question of appointing a deputy-receiver resident in Australia, and giving him power to make any necessary advances for carrying on the undertaking.

Wallace v. the Planet Electrical Engineering Company (Limited).

Judgment was given in this action on Saturday last by Mr. Justice Stirling. Plaintiffs held all the debentures to the amount of £2,500, which were issued in December, 1893. On February 26th an extraordinary resolution was passed for winding up the Company, and Counsel now asked for judgment.

His Lordship granted judgment in the terms asked, and gave plaintiffs liberty to apply in Chambers for any further consideration of the matter

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by Mr. J. C. Chapman, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

Note.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

April 16, 1895.

7,649. E. H. Crosay and O. M. Shaw. London. Improvements in and relating to electric arc lamps.*

7,657. W. M. McDougall, H. B. Adams and G. P. Smith. London. Improvements in secondary or storage batteries.*

9,565. Gray. Fixing electric insulators.
9,647. Nicolson. Telephones.
14,492. Adamson. Electric light photography.
15,129. Malignani. Evacuating incandescent lamp bulbs.
17,498. Benest. Electric alarm clocks.
19,934. Hübner. Galvanic batteries.
22,637. Hebard. Electric uterine battery.
8,224. Aldridge. Electric lighting.
10,172. Hopkinson. Electric rail or tram vehicles.
10,332. Suter. Arc lamps.
10,426. Kingdon. Dynamo-electric machines.
25,289. Ludvigsen. Primary battery.

1895.

1,949. Pye. Mat and electric alarm contact.
2,333. Adamson. Using electric light for photography.
3,062. Boynton. Electric locomotives.
3,086. Lake (World Flash Company). Telegraphic apparatus.
3,358. Wheless. Electric railway systems.
2,918. Devonshire (Steinmetz). Dynamo electric machines.
4,106. Lones. Dynamo electric generators and motors.
4,153. Johnson (Downes). Insulating electric conductors.

COMPANIES' MEETINGS AND REPORTS.

Eastern Extension, Australasia, and China Telegraph Company (Limited).

The forty-third ordinary general meeting of this Company was held on Wednesday, at Winchester House, under the presidency of Sir John Pender, G.C.M.G., M.P.

The SECRETARY (Mr. F. E. Hesse) having read the notice convening the meeting and the minutes of the last meeting, which were confirmed by the present meeting and signed by the Chairman as correct, the report of the Directors was taken as read.

The CHAIRMAN: Before asking you to approve the report I will, as usual, go over the accounts and show you the result of the working of the business during the last six months. The gross receipts for the half-year under review have amounted to £261,322, against £251,689 for the corresponding period of 1893 showing an increase of £9,633, which is entirely due to the large Government and Press traffic carried on with China and Japan since the commencement of hostilities between those countries. The working expenses have amounted to £89,740, against £76,574 for the corresponding period of 1893, showing an increase of £13,166. Of this nearly £9,000 is due to increased cost of repairs and maintenance of cables, which is always an uncertain factor, and the balance to the opening of new stations at Labuan and Sourabaya, the establishment of electric lighting at various stations, and other exceptional items. Comparing the figures for the whole year, the results are as follows:—The gross receipts for 1894 were £509,003, against £509,684, or practically the same as in 1893. The working expenses for 1894 were £170,035, against £154 803 in 1893, or an increase of £15,232, as already explained. The usual interim dividends have been distributed during the past year, making, with the dividend proposed to be paid to-morrow, a total payment of 5 per cent. for 1894. It is also proposed to pay a bonus of 4s. per share or 2 per cent., making a total distribution of 7 per cent. for the past year (applause). The balance of £89,686 has been carried to the general reserve fund, which now stands at £641,598 after charging during the past year £100,000, in part payment of the new Singapore-Hongkong cable. Altogether over a million and a quarter has been spent out of revenue since the formation of the Company on cable renewals, duplications and triplications, during that time we have not increased our capital, excepting to a very small amount (cheers). In terms of the trust deed, a further drawing by lot of 389 of the Company's Five per Cent. Australian Subsidy Debentures took place on the 1st ultimo for payment at par on July 1st next, when the debenture debt, which originally amounted to £640,000, will have been reduced to £209,500 (applause). The maintenance ships have as usual been

Digitized by Google

kept busy during the past half-year in efficiently maintaining our extensive system, but as most of the cables are duplicated, the revenue has in no instance been materially affected. Neither has the war in the Far East interfered with our cables, the service having been conducted as regularly as in time of peace. But for this we are doubtless indebted to the friendly but strict neutrality which the Company has maintained towards the two belligerents throughout the hostilities (hear, hear). As announced in the printed report, your Directors have lost in the decease of the Right Hon. Viscount Monck an esteemed colleague, who had been connected with the Company from its formation. For some time previously Lord Monck had been in a bad state of health, preventing him from actively participating in the duties of the Board, as I explained to the shareholders at a former meeting. Since I last had the pleasure of meeting you, another Inter-Colonial Postal and Telegraph Conference has been held in Australia, at which our guarantee arrangements with the Colonies were fully discussed. As you are aware, the Colonies have been passing though a severe financial crisis, and with a view to retrenching as much as possible, the Government of Victoria had given notice to the other guaranteeing Governments that she would probably withdraw from the guarantees at the end of the year. After full consideration, however, it was decided that the arrangements should be continued, with certain slight modifications, for a fixed period of at least five years, instead of being subject to cancellation at the end of any year, as was previously the case. Consequently, the cheap tariffs now in force between this country and Australia will remain unchanged during the next five years (applause). I think that that is a very pleasant announcement (hear, hear). It was hoped from certain remarks made to the Conference by the Queensland delegate that that Colony would join in the modified arrangement, and thus enable us to charge the same reduced rates to Queensland as the other Colonies enjoy; but up to the present time we have not received any definite announcement on the subject. The amount of guarantee Queensland would have to make up would be quite trifling compared with the advantages she would derive from the reduction of tariffs, and I still hope she will see the advisability of coming into the arrangement (hear, hear). With regard to the Pacific cable, I daresay you have heard a great deal about it, as we all have, and were I to give you my opinion upon it I should be virtually repeating what I told you at the last two half-yearly meetings. I do not think it has advanced one step further than it was when I last addressed you. This project was also fully discussed at the Hobart Conference; but the resolution submitted by the Queensland delegate for *practically* dealing with it was unsupported and withdrawn, and an amendment was subsequently passed simply reaffirming the desirability of cable communication across the Pacific, and urging the various Governments to take steps to further the project at the earliest opportunity. Judging from the telegrams appearing from time to time in the newspapers, Canada is losing no opportunity of keeping the project before the public; but until the Colonies, including Canada herself, are in a better financial position, and are agreed amongst themselves as to the details of the scheme, which is very far from being the case at present, I do not believe that any real progress will be made in the matter (Hear, hear). I have received a letter—and only one—from a shareholder, expressing disappointment at not having been invited to take part in the celebration of our twenty-fifth anniversary, but when I mention that there are nearly 16,000 shareholders in the Eastern and Extension Companies, it will be seen that it would have been physically impossible to ask them all, in addition to the many customers, Government officials, and other representatives who it was desirable to invite (hear, hear). The principle we adopted with regard to the shareholders was to invite only those whose names were on the share register at the formation of the companies, and of these, holders of 100 shares and upwards were asked to the banquet, and the remainder to the reception. By this means we were enabled to keep the number within reasonable limits, and as the principle was a perfectly fair one, it should be satisfactory to all concerned (hear, hear). I feel quite sure that the shareholder will be satisfied with this explanation. and I only regret that he was not present, owing to the circumstances of the case. I think I have laid before you to-day a most satisfactory account of the past six months' working (applause). We occupy a position which is very unique. We have done our work remarkably well, and have thus secured during these years the full confidence of the telegraphing public (Cheers). We have paid you a fair dividend, but not an exorbitant one, although one which is much larger than is generally paid by many of the companies which have been floated during the last 25 years (hear, hear). I believe that we have established for you a thoroughly sound system—a system which the world could not now do without (hear, hear). The work we do is extremely popular, and we have done very much to extend not only trade throughout the world, but political influences also, and we have also brought nearer to the mother country all those countries which have sprung from her. I think it is a very fine position for the shareholders, and the Companyas (applause) to occupy. During all these years we have never had one fault found with us for doing anything that was not perfectly straightforward in the conduct of our business. I therefore speak with some pride, and I say that the accounts submitted to you to-day are accounts on which I congratulate you, while I think we are also to be congratulated by the shareholders for being able to present them with such a gratifying statement (cheers). With reference to my remarks about the Pacific cable, I may say that it is not our business to oppose cables, but to carry cables to every point where trade is established, and our flag flies (hear, hear). That is a leading part of our policy, and we shall continue it. Confidence generally is reposed in us, and great sympathy is shown towards us. As I have just told you, the Australian Colonies have extended their guarantee with us for a period of five years, but I do not believe, after all, it will cost them much, if anything.

A SHAREHOLDER: Will you tell us how much the guarantee has cost the Colonies already?

The CHAIRMAN: It has cost them up to the present time between £50,000 and £60,000, but I do not think it will cost them much in future, if anything. The Colonies, as you know, do not always agree with one another. Our business is to get them to agree with us, and I think we have had singularly good fortune in having the hearty co-operation not only of the Colonies at headquarters, but of their representatives—the Agents-General—in England. I hope my reply to you is satisfactory.

The SHAREHOLDER: I only wanted to know, because the prospect of their continuing the guarantee will depend a good deal upon the weight which it throws on them.

The CHAIRMAN: I give them the credit for continuing the arrangement. I think I have now said everything that I had intended to say, but if any gentleman has any question to put to me regarding any point upon which I have not touched, I shall be glad to answer him.

The SHAREHOLDER: Would you have patience with me if I ask you if you ever take into consideration whether you will give us more than 7 per cent. dividend?

The CHAIRMAN: I do not think it would be good for you if we did (laughter). I think I could satisfy you on that point in a private conversation. The 7 per cent. which you are getting to-day is a handsome dividend, and compared with what it would have been a few years ago it is now very much higher. What I want to do is to secure to you this good and satisfactory dividend, and the more that we can build up the reserve fund and strengthen our system without increasing our capital, the more beneficial it will certainly be to the shareholders (hear, hear). That is our policy, and we are following it with a great deal of care and caution. I now move—

"*That the report and accounts of the Directors n w submitted be received and adopted, and that a dividend be now declared of 2s. 6d. per share, together with a bonus of 4s. per share, both free of income tax, payable on the 2nd inst., making, with the previous distributions, a total payment of 7 per cent for the year 1894.*"

The Marquis of TWEEDDALE: I beg to second the resolution.

Mr. W. GRIFFITH: I am sure we are all indebted to you for the very clear and lucid statement you have made to us, and I think that the policy which you have enunciated must commend itself to the shareholders at large. It is better to keep a good reserve fund, so that you may be able to develop our system without increasing our capital. It is evident that that will increase the value of our shares, and while you continue the payment of this dividend of 7 per cent., I certainly think there is no cause for complaint. With respect to the twenty-fifth celebration, I think it might have been recorded in a more permanent way, and in a way which would have been more beneficial to the Company, if a medal had been struck commemorating the great development of submarine telegraphy, or if a small book had been published containing views of the different places at which we stop, with a short historical account of our different stations. I think that we might have improved the position of our Company by circulating these medals and books among the public at large, as well as among the shareholders. But, of course, this is a question of detail. It seems to me that it would have been of more permanent benefit to us had such a course as this been followed, instead of giving a dinner and a reception, which gratify a few for one particular night.

The CHAIRMAN: There are two ways of advertising—the sensational and the sober (hear, hear). As a rule I like something that is permanent, but we cannot always be dealing with hard and dry facts. We must have a day of joy in our lives occasionally, and after 25 years' dry work, I think it was not a wrong thing for us to have a little jollification over it (hear, hear. and laughter). My impression is that it has done more for our Company and its work throughout the world than anything else we could have thought of. If we had struck a medal and given one to each of our shareholders, it might have cost 5s. or 20s. each, and thus represented a much larger expenditure than was incurred, and we should never have heard anything more about it. The money would have been spent, and the medals would have been practically useless, but this dinner will live in the memory of the present century (cheers). It was very highly appreciated (hear, hear). I have done a great deal of good work myself at a dinner, and I know what can be done on such an occasion where half-a-dozen thoughtful men meet. It is marvellous how things progress at a dinner (laughter).

Mr. JOHN NEWTON: I should just like to say a word or two on this subject, for I think that you acted quite rightly in connection with this banquet. In my early experience of submarine telegraph enterprise, I happened to know a certain gentleman who asked Mr. Cyrus Field this question: "How did you come to accomplish the carrying out of a cable from England to America?" He replied, "I sold my horses and carriages, and I gave a lot of banquets in New York." That statement was given to me soon after it was made by Mr. Field. Everyone knows what immense advantages arise from a banquet—of course, judicially given; and this banquet in celebration of our 25th anniversary was one of the most successful that has ever been held (hear, hear). I am perfectly satisfied with the position of the Company, and it has shown an example of strengthening its position and making itself secure, and you actually now say that you do not think it wise to increase the dividend. I think, however, that there is a way by which that object might be accomplished. Your reserve fund is one of the most splendid of any joint-stock company in the kingdom. No railway company makes its new lines and does its repairs to the extent we do out of reserve fund. A railway company, if it makes a new line, charges its cost to capital. Could you not see your way to giving us a bonus by issuing shares at par when you lay a new line, as you sometimes do, thus creating important feeders for the main system. You recently opened a cable at Borneo, which I am sure will be of immense advantage later on. You might possibly see some way of acting upon this suggestion. The Directors have done so well that to that fact we may attribute the circumstance that so little is said on this side of the table when we meet (hear, hear).

Digitized by Google

The CHAIRMAN: Do you not think it very good policy, Mr. Newton, to leave well alone? We are doing uncommonly well. If we were going back in any way, and we required the spur, I should be very glad to entertain any proposition; but a very great statesman, when he was asked to go on, said, "Do you not think it better to leave well alone?" I think that the bulk of the ladies and gentlemen I am addressing now are satisfied with their 7 per cent. dividend, and will let well alone (cheers). I like a good dividend; but I do not care about having a good dividend to-day and no dividend next year. I want you to have confidence in this concern, that you may know that the dividend you receive to-day you will receive in years to come (hear, hear). That is our policy, and in these days of competition we have to keep our eyes open to see that things are not done which will lessen instead of increase our dividend. The policy we are pursuing of increasing our power without increasing our capital is one which I think no shareholder should object to; and I believe that the bulk of the shareholders of this Company will agree with me when I say, Let well alone (hear, hear). He then put the resolution, which was carried unanimously. Continuing, he said, I now propose "That Charles William Earle, Esq., who now retires by rotation, be and is hereby re-elected a Director of this Company."

Mr. F. A. BEVAN seconded the motion, which was unanimously carried.

The CHAIRMAN: I now propose "That George Garden Nicol, Esq., who now retires by rotation, be, and is hereby re-elected a Director of this Company."

The Marquis of TWEEDDALE seconded the motion, which was carried unanimously.

The CHAIRMAN: It was not necessary for me to say a word in regard to these two gentlemen, who have been connected with the Company from its inception. They have taken part in the good management of the Company, and I think you must feel that in re-electing them to-day you are paying them the compliment of exhibiting your confidence in them both as regards the past and the future. The next resolution, which relates to the appointment of auditors, will come from the shareholders' side of the table.

Mr. JOHN NEWTON: I propose "That Messrs. Deloitte, Dever, Griffiths and Co., and Messrs. Welton, Jones and Co., be and they are hereby elected auditors for the ensuing year at a remuneration of £100 each." I think that our auditors' certificate in this case is a very gratifying one, for they simply say, "Audited and found correct."

Mr. G. HEWAT seconded the motion, which was carried unanimously.

The CHAIRMAN having intimated that that concluded the business,

Mr. GIBB said: I move that a cordial vote of thanks be given to the Chairman and Directors for their able conduct of our affairs. I propose this resolution formally now, but really all the remarks that have come from this side of the table have substantially meant a vote of thanks. We all recognise that the work of the Company has been admirably done, both in large matters of policy, as in the Hobart Conference, and in small matters, comparatively, such as our 25th anniversary celebration. I propose this vote of thanks with great cordiality.

A SHAREHOLDER seconded the motion, which was carried by acclamation.

The CHAIRMAN: You have always been very kind to my colleagues and myself, and I can assure you that we have always appreciated your good-will and confidence. I am quite satisfied that no company can be prosperous if the shareholders are pulling one way and the Directors another (hear, hear). It has been our desire from the beginning to put you in possession of all the information that we considered it desirable you should have, and there is really very little that we know with which you are unacquainted. Moreover, if there is anything that you do not know at the moment you will hear of it very soon afterwards, because we carry on our diplomatic relations in such a spirit that they show themselves. At this very meeting we have been able to tell you with pleasure and pride that we have accomplished certain things since I last had the gratification of addressing you (hear, hear). I think we have made such arrangements with the Australian Governments as to show that they have thorough confidence in us, while we have every desire to benefit them. I thank you again for the confidence you repose in us.

The proceedings then terminated.

Submarine Cables Trust.

The thirty-fourth ordinary annual meeting of the certificate holders in the Submarine Cables Trust was held at the offices, Winchester House, Old Broad-street, yesterday (Thursday), Sir John Pender, G.C.M.G., M.P., presiding.

The SECRETARY (Mr. A. Brodrick) having read the notice calling the meeting and the minutes of the last meeting,

The CHAIRMAN said: You have had the report in your hands for some days, so I suppose you will take it as read, but before you do so I wish to make one amendment in it. It says, "The meeting will have to elect two auditors for the current year. Mr. John G. Griffiths and Mr. John Gane offer themselves for re-election." I wish it to be understood that it is the firms of these two gentlemen who are to be elected. The reason why I want this alteration made is that it might happen that Mr. Griffiths was away and that Mr. Gane was away, in which case any partner in their firms could do the audit. As it stands it binds us now to these two gentlemen to do the audit, and this might inconvenience us. It did inconvenience us on one occasion, and having experienced that inconvenience, the other companies in which these gentlemen act as auditors have made the alteration which I propose now to introduce in this Company. That is the only amendment which I have to ask you to approve being made in the report; but before I ask you to accept the resolution which I shall propose, I will give you, as has always been done on these occasions, a few figures showing you the position we are in to-day. The revenue for the past year amounted to £21,464, as against £22,592, or a decrease of £1,128. This is owing to our having received a smaller dividend for the current year on our investment in the Anglo-American Company. The expenses for the year amounted to £1,194, as against £1,301, or a decrease of £107. As will be seen from the report, the trustees regret to record the death of their colleague, Lord Monck, who was one of the original founders of the Trust. This in the principal cause of the reduction in the expenses. I may, however, mention that the total expenses are £805 less than the amount provided by the trust deed. Our revenue for the past year, including £240 brought forward from the previous year, has enabled us to meet two coupons of £3 each, but we have not been able during the year to pay anything additional off the remaining portion of the overdue coupon. There is therefore still a balance of £1. 5s. in arrear, but this, we anticipate, will be paid about the middle of July next. The present market value of the investments held by the trust, as compared with the cost price, shows an increase of over 52 per cent. The 3,381 certificates remaining uncancelled are therefore worth on this basis £150 each. This I think you will consider a very satisfactory condition for the Trust to be in, notwithstanding the regrettable decrease in the income divisible from our investment in the Anglo-American Company. There is very little more for me, gentlemen, to state further. As you know, the constitution of this Company is rather a peculiar one. If it went on long enough the oldest holder would be the possessor of the whole concern. However, that is a long way off. I shall not be present, and I doubt if any one here will be, but it is a very good legacy to leave behind us. I now beg to move—

"That the report and accounts of the trustees to April 15, 1895, submitted to this meeting be, and they are hereby received and adopted."

Mr. KENNETH L. M. ANDERSON seconded the motion, and it was carried unanimously.

The CHAIRMAN: This is a very quiet concern. When you see that the telegraphs are prospering you may be quite sure that this Company follows in the same direction. Our shares have advanced very considerably of late, and we have been purchasing them for some of our other Companies. I think that, on the whole, it is a good investment, and one so closely associated with the prosperity of the telegraphs that I can only say when they flourish we shall flourish with them. The next business is the election of auditors.

On the motion of Mr. LUCAS, seconded by Mr. E. CUNLIFFE OWEN, Messrs. Deloitte, Dever, Griffiths and Co., and Messrs. Gane and Jackson, were appointed auditors of the Trust for the current year.

Mr. LUCAS then proposed a vote of thanks to the Chairman for the very clear statement which he had made to the meeting, showing the very satisfactory condition of the Trust.

Mr. CUNLIFFE OWEN seconded the motion, and it was carried unanimously.

The CHAIRMAN: On behalf of my colleagues and myself I beg to return you thanks. I have had to do with the Company from its inception. It has gone on, I think, very steadily and quietly, and I believe it has a very good future before it. So far as we Directors are concerned we shall keep it out of trouble, if possible, and do everything we can to make it prosperous.

The proceedings then terminated.

Indo-European Telegraph Company (Limited).

The twenty-eighth ordinary general meeting of the members of this Company was held at Winchester House, Old Broad-street, on Monday under the presidency of Mr. J. Herbert Tritton.

The CHAIRMAN having declared the meeting duly constituted, called upon the Managing Director to read the notice convening it.

The MANAGING DIRECTOR (Mr. W. Andrews) having read the notice, the seal was affixed by the Chairman to the register of shareholders, and the report of the Directors was taken as read.

The CHAIRMAN: I have now to move—

"That the report and accounts now submitted be received and adopted, and that a dividend be and is hereby declared for the half-year ended December 31, 1894, of 17s. 6d. per share, making, with the interim dividend already paid, 6 per cent. for the year, and a bonus of 20s. per share, both free of income tax, making in all 10 per cent. for the year."

It is once more my pleasing duty to congratulate you upon the outcome of the working of the Company. The past year shows, it is true, a slight falling off in the business as compared with the year 1893, the total decrease in the traffic receipts from all sources amounting to some £3,750. The expenses are on all accounts £64,838, and compare with £64,959, so that practically they are the same. Following the prudent course which the shareholders have repeatedly approved, we have, however, written down certain items, and the actual expenses of working the system and maintaining the lines are somewhat lower. The falling off—or, as I should perhaps say, the fluctuation—of the message business has occurred mainly in the trade with India, and the loss would have been greater but that it has been partially compensated for by increases in other sources of revenue. You will no doubt remember that on a previous occasion I drew your attention to the fact that with Indian business there cannot be the same continuous and always increasing traffic which is expected, and which, indeed, almost invariably makes itself manifest with differently constituted communities, such as Australasia. I am pleased to tell you that the agreement with Australasia, under which the Governments guaranteed a proportion of the loss arising from the introduction of the low tariffs—without which guarantee these tariffs could not have been introduced—has been extended, and will now run for another five years. Certain modifications of the arrangement

Digitized by Google

have been effected, but these are not likely to act prejudicially on our receipts, and I think I may congratulate you upon the establishment for so considerable a period of these low rates. Our business continues to be performed by our own and the Government lines in connection with ours in a manner which appears to be quite satisfactory to the mercantile public. We have no complaints, but many expressions of satisfaction; and those who actually use the wires, and who may therefore be supposed to know their own business and their own needs the best, in all the large number of letters exchanged with our Company, seem to feel that the return given by the Governments and the Company in the costly and efficient working and maintenance of their lines under circumstances, you will remember, of great difficulty, through pretty nearly all the extremes of climate in the world, is completely satisfactory. In fact, no exertion is ever wanted on our part to run abreast or even ahead of the requirements of the mercantile world, and we therefore feel some confidence that we shall continue to maintain with our customers the relations which have proved so agreeable down to the present time. Our whole system continues in excellent working order throughout. Our reserve fund also continues to flourish, owing, I may honestly say, to the extreme care with which the investments on that account have been, and, I trust, will continue to be made. It may interest you to know that at the present moment the investments if sold would realise upwards of £20,000 more than their cost price. There is just one other point which I think I ought to touch upon, seeing the very high price that our shares have reached, and that is the terminability of our concessions, which, as most of you are doubtless aware, run out in the year 1905—perhaps I should say are liable to terminate in the year 1905. In the concession to which I am now more particularly referring the clause relative to this particular point says that the Company is bound to come to terms with the Government before the date at which the concession would otherwise expire, and the lines pass over to the Government. Consequently, though I feel bound, under the circumstances, publicly to call attention to this point, I must not be understood, if you please, to do so with any pessimistic views whatever. Anything of that sort, indeed, is far from my thoughts, but I mention it because I feel that there may be some among our shareholders who are unacquainted with the details of the concessions. We shall, of course, the moment the proper time is held to have arrived, enter upon the negotiations which are pointed out in the concession itself as the necessary and proper course for us to adopt, and you may depend upon it that we shall be mindful of the great interests we have to protect. I need not repeat how much the Company owes to the most efficient services of our Managing Director, Mr. Andrews—who has this year completed his twenty-fifth year of connection with us—and also to Mr. Moll, Mr. Pagenkopf, and in fact to the whole of our staff at home and abroad. You could not be better served, we are well assured. The two Directors who retire are Major-Gen. Tremenheere and myself; but both offer ourselves for re-election. I now beg to propose the resolution which I submitted at the opening of these remarks.

Major-Gen. G. B. TREMENHEERE, R.E., seconded the resolution.

Mr. MacANDREW observed that the Chairman had stated that in regard to the concessions the Company was bound to come to an understanding with the Government before 1905. He would like to know what Government was referred to.

The MANAGING DIRECTOR intimated that it would not be advisable to go into details with respect to the different Governments.

A SHAREHOLDER inquired whether all the concessions would expire at the same time.

The CHAIRMAN: No, they do not all expire at the same time.

The CHAIRMAN then put the resolution to the meeting in the usual way, and it was carried unanimously.

Mr. C. W. EARLE next proposed the re-election as Directors of Mr. J. Herbert Tritton and Major-Gen. Tremenheere. He did not think it necessary to say a word in praise of either of these gentlemen, who had for so many years been well known to the shareholders.

Mr. C. HOLLAND briefly expressed his pleasure at seconding the motion, which was carried unanimously.

The CHAIRMAN, on behalf of Major-Gen. Tremenheere and himself, said they would be glad to devote themselves to serving the Company for the future as they had done in the past, and he thanked the shareholders for their re-election.

On the motion of Mr. ST. LAWRENCE SMITH, seconded by Mr. MacANDREW, the retiring auditors, Messrs. C. F. Kemp, Ford and Co., were re-elected.

Mr. MacANDREW then proposed a vote of thanks to the Chairman for presiding and to the Directors and staff for their management of the Company's business.

Mr. HÖLTZER seconded the motion, which was carried unanimously.

The CHAIRMAN acknowledged the vote, and the proceedings then terminated.

Oriental Telephone and Electric Company (Limited).

The first annual general meeting of this Company was held on Monday, April 29, 1895, at Cannon-street Hotel, Mr. William Addison presiding.

The SECRETARY (Mr. Alexander B. Chalmers) read the notice convening the meeting.

The CHAIRMAN said: Gentlemen, before moving the adoption of the report and accounts, I am glad to tell you that the reconstruction of the Company has been accomplished satisfactorily, and with as little expense as could have been anticipated. We are now fairly launched on our new career, with all the shares of the Company of the same value, and without a fraction of liability on any of them. This result has not been attained, however, without considerable trouble and anxiety to your Board, but I feel sure its effects will be conducive in many ways to the welfare of the Company; there are now no conflicting interests. You will recollect that the liquidators of the old Company made a distribution last year to the shareholders equal to nearly 4½ per cent. per annum on the amount of the new capital, and for a period of 14¼ months, consequently the dividend now to be paid will only be for about 9¾ months, as explained in the report. I am glad to say that the business generally is progressing, and although the capital of the Company is more than that of the old Company, on which dividends were paid, the rate per cent. of the dividend is higher than in any former year. In dealing with the net amount available for distribution, I think you will all agree that the policy of the Board in writing off the whole of the preliminary expenses of the present Company is a sound one. The subsidiary companies in India call for little comment from me. Their revenues, I am glad to say, are improving, and should silver rise in value we may expect still better remittances on account of the shares which we hold in them. Athough exchange has told hardly against the business of the China and Japan Telephone Company, we hope now that the war has been concluded, the business of that Company may be extended. I do not think there is any other point in connection with the report to which it is necessary for me to refer. Turning to the balance sheet, you will notice on the credit side the item of goodwill and expenditure on exchanges is set down at £69,189. 0s. 6d., which your Directors think a moderate figure. You will see that the valuation of the shares, &c., held in subsidiary companies, is set down at £86,713. 2s. 6d., against £91,937. 14s. 10d. in the old Company's balance sheet, the difference being occasioned by the writing down of the value of the rupee securities from 1s. 5d. to 1s. 1d. exchange. The only other item to which I shall refer is that of £13,004 0s. 7d. in Two and Three-quarter Consols, which have been taken in at the value put upon them by the old Company, viz., cost price. In conclusion, I think under all the circumstances the shareholders of this Company may congratulate themselves upon owning a property which is thoroughly sound. If there is any point to which I have not referred, and on which anyone present is desirous of information, I shall be glad to give it.

Mr. BENNETT PELL asked for the total market value of the shares held by the Company in subsidiary companies. According to quotations in the newspapers he found that the shares in the Bengal Company were quoted at 100 rupees, and that, taken at 1s. per rupee, would work out at about £28,000 for these shares only. Then there were the Preferred shares in the Telephone Company in Egypt, the value of which worked out at about £60,000, so that they had in those two items alone more than the amount at which the whole of the shares in subsidiary companies stood at in the balance sheet.

The CHAIRMAN: I do not see how you can value the Egyptian shares as there is no market for them. The shares in the Bengal Company are taken at the valuation put upon them some years ago.

Mr. PELL remarked that he simply wanted to point out that their property was undervalued.

Commander HANNAY, R.N., said it appeared to him that the report was eminently satisfactory, considering that they had brought in the Vendors' shares, and were still able to pay a substantial dividend. One thing he could not make out was why there did not appear to be any improvement in the value of their shares on the Stock Exchange, although their Company had progressed.

The CHAIRMAN: I do not quite agree that no improvement has taken place in our shares, inasmuch as a few months ago they stood at 10s. per share, and I believe they are a little higher now. If there is no other question, I will move the following resolution:—

"That the Directors' report, together with the accounts and balance sheet to December 31, 1894, be approved and adopted, and that a dividend at the rate of 4½ per cent. per annum, free of income tax, be declared on the paid-up capital of the Company for the period from March 12th to December 31, 1894."

The resolution was agreed to *nem. con.*

Mr. B. ST. JOHN ACKERS moved the re-election of the Chairman as a Director, which was seconded by Commander HANNAY and agreed to.

The re-election of Mr. T. Lloyd, proposed by the CHAIRMAN, and seconded by Mr. HENRY GREWING, was also approved. The re-election of the auditors, Messrs. Deloitte, Dever, Griffiths and Co., at a fee of 50 guineas, having been carried,

Commander HANNAY proposed, and Mr. SEAMAN seconded, a vote of thanks to the Chairman and Directors, which was unanimously accorded, after which the proceedings terminated.

London Platino-Brazilian Telegraph Company (Limited).

The following report of the Directors of this Company to December 31st last will be presented to the seventeenth ordinary general meeting, to be held at the offices, Blomfield House, 85, London-wall, London, E.C., on Monday next, May 6th, at 12 o'clock:—

The total earnings for the period amount to £20,674. 6s. 8d., as against £24,585. 7s. 3d., a decrease of £3,911. 0s. 7d. compared with the previous year. The working expenses amount to £8,327. 8s. 3d., as against £8,606. 19s. 2d., a decrease of £279. 10s. 11d. Including the amount brought forward from 1893 (£179. 10s. 9d.), the balance to the credit of the revenue account is £12,526. 9s. 2d.; from this has been deducted £6,000 for debenture interest; this leaves, after placing £1,500 to reserve, £5,026. 9s. 2d. The Directors recommend that a dividend at the rate of £1. 5s. per cent. per annum (2s. 6d. per share) be paid for the year, carrying forward £332. 19s. 2d. The dividend will be paid on May 6th.

The lines of the Company are in good working order.

The retiring Directors are Mr. John Coppen and Mr. C. W. Earle, who offer themselves for re-election, as do the auditors, Messrs. Deloitte, Dever, Griffiths and Co.

NEW COMPANIES, STATUTORY RETURNS, &c.

JANDUS ARC LAMP AND ELECTRIC COMPANY (LIMITED).—This Company was registered on April 24th, with a capital of £20,000, in £10 shares, to acquire from John B. Barton certain patents for "improvements or connected with electric arc lamps," and the benefit of all improvements in arc lamps already made or to be made by John B. Barton and William Jandus, and for that purpose to enter into an agreement made February 20, 1895, between J. B. Barton and A. A. Gillies (for the Company), to manufacture, sell and supply Jandus electric arc lamps, and other electric lamps and apparatus, cables, conductors, insulators, globes, carbons, plant, machinery, and to carry on the business of an electrical company. The subscribers, with one share each, are: Bernard M. Dfake, T. A. Earle, E. N. Galloway, S. Garnett, J. T. Petrocokino, F. Reddaway, and A. Gillies. The first Directors are Bernard Drake, T. A. Earle, E. N. Gallowry, J. M. Gorham, J. T. Petrocokino, F. Reddaway, and J. B. Barton.

LAMP MANUFACTURING COMPANY (LIMITED).—This Company was registered on April 26th, with a capital of £20,000, in 10,000 Preference and 10,000 Ordinary shares of £1 each, to enter into an agreement with the Lamp Manufacturing Company, and the liquidator thereof (Mr. Harvey E. Preen), for the acquisition of the old Company's business, and to carry on the business of manufacturers of and dealers in lamps of every description, mechanical and electrical engineers. &c.

R. NAPIER AND SONS (LIMITED).—This Company has been registered with a capital of £250,000, in shares of £10 each, to carry on the business of shipbuilding and engineering upon the Clyde or elsewhere, and to acquire the goodwill of the business of R. Napier and Sons, engineers and shipbuilders, at Glasgow and Govan. The old firm constructed the cable steamers "Electra," "Mirror," "Amber," and "Recorder."

HUBERT GRENFELL (LIMITED).—An agreement with Gilfrid G. B. Cresswell, Evan M. Protheroe, Hubert H. Grenfell, Robest H. Pringle and Peter Strickland, provides for the acquisition of the rights and interests of these gentlemen in connection with the manufacture and sale of electric night lights and improved curved bar sights for ordnence, as from January 1, 1895, in consideration for the allotment as fully paid of 3,250 Ordinary shares of £1 each. An agreement with Capt. H. H. Greenfell, R.N., provides for the sale to the Company of the vendor's interest in British patents No. 13,549 (1888) for "improvements in apparatus for aiming or directing ordnanee; No. 7,711 (1889) for "improvements in sights"; No. 9,423 (1891) for an improved holder of electric incandescent lamps"; No. 934 (1892) for "improvements relating to sighting and indicating apparatus for ordnance;" and No. 10,637 (1893) for "improvements in sighting apparatus for guns"; and the French, Belgian, German, Austrian, Italian, Swiss, and United States patents for the same, subject to agreements with the persons mentioned in the contract described above, with Sir W. G. Armstrong, Mitchell and Co. (Limited), with Fried Krupp, and with G. Canet, of Paris, and also the business carried on by the vendor in connection with the said patents, in consideration for the allotment as fully paid of 5,000 Ordinary shares of £1 each.

HOUSE-TO-HOUSE ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of this Company to February 22nd has been filed. The nominal capital is £350,000, divided into 57,900 Ordinary, 100 Founders', and 12,000 Preference shares, all of £5; 8,322 Ordinary, all the Founders', and 5,000 Preference shares have been taken up, and 1,000 Ordinary and the Founders' shares have been issued as fully paid. The full amount has been called and paid on the remaining 7,322 Ordinary and 5,000 Preference shares.

KESWICK ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company to March 14th has been filed. Out of a nominal capital of £5,000, in £1 shares, 3,420 have been subscribed for and allotted, and upon each of these the full amount has been called and paid.

LANCASHIRE AND YORKSHIRE ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of this Company, to July 12, 1894, was filed on April 2nd. Out of a nominal capital of £100,000, in £5 shares, 127 have been taken up, upon which a call of £2. 10s. per share has been made.

LIVERPOOL ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of this Company, to February 22nd, has been filed. The nominal capital is £300,000, in £5 shares, and 50,000 of these shares have been subscribed for and allotted. The full amount per share has been called, resulting in the payment of £250,000.

LOWCOCK, HILL AND CO. (LIMITED).—The statutory return of this Company to April 19th has been filed. The nominal capital is £15,000, in £10 shares, and 407 have been taken up. Of these 400 have been issued as fully paid to G. W. Lowcock and G. Hill, electrical engineers, of Manchester. The full amount has been called on the seven signatories' shares, but nothing has been paid thereon.

MAZARRON ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company to March 14th has been filed. The nominal capital is £15,000, divided into 500 £800 per cent. £10 Preference shares and 10,000 £1 Ordinary shares, and of these 131 of the former and all of the latter have been taken up; 9,993 Ordinary shares have been issued as fully paid, and the full amount has been called and paid on the remainder.

MERVEILLEUSE ELECTRIC ARC LAMP SYNDICATE (LIMITED).—The annual return of this Company to April 8th has been filed. Out of a nominal capital of £15,000, in £1 shares, 10,107 shares have been taken up, and 9,000 of these have been issued as fully paid. The full amount has been called on the remaining 1,107 shares, resulting in the payment of £725, and leaving £382 as arrears.

NOTTING HILL ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of this Company to March 12th has been filed. The nominal capital is £100,000, consisting of 6,452 Ordinary, 550 Founders', and 2,998 Ordinary Preference shares of £10 each. All the Ordinary and Founders' and 1,737 Ordinary Preference shares have been subscribed for and allotted. The full amount has been called on all the Ordinary and Founders' and 1,370 of the Ordinary Preference, and a call of 10s. per share has been made on the remaining 367 Ordinary Preference, resulting in a total payment of £83,903. 10s.

CITY NOTES.

ALUMINIUM.—The report of the Aluminium Industry Company, of Neuhausen, Switzerland, for last year shows a profit of £36,953, as against £31,500 in 1893, a dividend at the rate of 10 per cent. being declared.

BERLINER ELEKTRICITATSWERKE.—The capital of this Company has been increased by 3,600,000 marks (£180,000), so that the total capital is now 12,600,000 marks (£630,000).

BIRMINGHAM CENTRAL TRAMWAYS COMPANY (LIMITED).—Mr. J. Ebbsmith has retired from the Chairmanship of this Company, and Mr. Neale has been elected in his stead. It is stated that Mr. Ebbsmith will remain on the Board as an ordinary Director.

BULUWAYO (SOUTH AFRICA).—Amongst the objects of the Buluwayo Waterworks Company (Limited), prospectus of which is issued this week, and for which a capital of £200,000 is invited, are to supply to the town of Buluwayo and the suburbs thereof, electric current, and the erection of the necessary plant for the generation thereof, laying of mains, &c. Shade of Lobengula, what a change was there.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended April 28th were £900, as against £901 in the corresponding week of 1894, being a decrease of £1. The total receipts for the half-year amount to £16,119, against £15,514 for the corresponding period of 1894, an increase of £605.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of April, 1895, amounted to £67,046, against £56,751 in the corresponding period last year, an increase of £10,295.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of April, 1895, amounted to £38,080, and to £38,802 in the corresponding period of last year.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 28th ult. amounted to £1,121. The amount for the corresponding week last year was £667.

LUDWIG LOEWE AND CO. (LIMITED), BERLIN.—At a recent meeting of shareholders of this Company a dividend of 20 per cent. for 1894 was declared. It was also decided that the original capital should be raised by 2,250,000 marks (£112,500), for the purpose of building new works for the manufacture of electrical machinery, which has hitherto had to be bought from foreign makers. The issue of Four per Cent. Bonds of the amount of 10,000,000 marks (£500,000), to replace the existing Four and a-Half per Cent. Bonds of 6,500,000 marks (£325,000), and to increase the Company's working capital, was also agreed upon.

MIX AND GENEST (LIMITED), BERLIN.—At a meeting of the shareholders of this Company, held last week, a dividend of 11 per cent., payable forthwith, was declared for the year ended December 31st last. The gross profit amounted to 434,552 marks, which, after deducting expenses amounting to 152,391, leaves an available profit of 282,161. After writing 48,000 marks off plant and tools account, and 40,000 marks off patents (which latter stands now nominally at 1s. only), and after transferring 7,000 marks to workman's benevolent association, a balance of 690 marks was carried forward to next account. The Directors state that the works have been busy since the beginning of the present year, with large orders from various Governments, as well as from their regular trade customers, and the prospects are very promising, and the working staff, numbering nearly 1,000 hands, are fully employed. The Company have concentrated their various works since the beginning of January into their new factory, upon which, including outfit, 1,100,000 marks has been expended. The new building is fitted up with the most modern machinery and appliances, and sufficient adjoining land has been acquired for any ultimate extension that may be required.

UNION ELEKTRICITATS-GESELLSCHAFT OF BERLIN.—This Company considerably improved its financial position in 1894, and after writing off the deficit of 1893—£8,500—has now declared a dividend of 8 per cent. on its capital of £75,000.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—Yesterday (Thursday), the Directors of this Company, at their meeting, after placing £8,000 to reserve and £5,000 to the debenture redemption fund, and subject to audit, decided to recommend to the forthcoming meeting of shareholders a dividend of 6s. per share, free of income-tax. This will give 6s. to the Ordinary, 4s. 6d. to the Preferred Ordinary, and 1s. 6d. to the Deferred Ordinary shares, which, with the interim dividend paid in November last, makes a total distribution of £3 per share for the year ended December 31, 1894. The traffic receipts for the week ended April 26th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), amounted to £3,178, and to £2,871 in the corresponding period of last year, being an increase of £307.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 886. [No. 2: Vol. XXXV.] FRIDAY, MAY 10, 1895. PRICE SIXPENCE.

NOTES.

It would appear as if the question of the duration of municipal electric lighting loans were at last settled. The periods agreed upon by the Treasury and the London County Council, viz., 50 years for land, buildings, culverts, and bare copper mains, and 20 years for all other items, were not to the liking of the London Vestries; and pertinacity has once more won the day. The Lords of the Treasury have compromised the matter. In future municipal electric lighting loans may be granted for 42 years, provided that the cost of all renewals of plant, &c., bought with money raised for this term, be defrayed out of revenue or from a renewal sinking fund. If it prove practicable to keep local authorities to the conditions of the bond, the requirements of sound finance would seem as likely to be complied with by this arrangement as by the one originally promulgated.

There is no work which deserves better of the electrical industry than that of bringing to the notice of municipal engineers, and their employers, the manifold advantages of electricity as a lighting and power agent. The main fact to drive home on such occasions is that the business, if properly managed, can be made an assured financial success. The unvarnished, but thoroughly convincing tale, which Mr. Wright had to tell the Incorporated Association of Municipal and County Engineers at their recent meeting at Brighton should, therefore, have considerable influence, since his discourse on the points of interest in the development of electric supply at Brighton bristled with figures, but not with technicalities. Brighton, Mr. Wright took no little pride in pointing out, is a town of considerable electro-historic interest. It was the first town in England to possess a central station erected for the express purpose of affording an electric supply, and it also led the way in the use of meters. It has, moreover, seen the rise—and fall—of many different systems of distribution. First came series arc lighting, then the multiple-series system, the house-transformer system, the two-wire system, the three-wire continuous system; and, lastly, a happy combination of an alternating with a continuous supply. Last, but not least, Brighton has given its name to the well-known differential method of charging which is destined to do much towards lightening the load on the central station manager's mind.

Dr. Fleming makes some useful suggestions in our present issue with regard to the representation of periodic currents by polar diagrams. The chief objection to the use of polar curves is that they are not so well understood as the more ordinary ones in which rectangular co-ordinates are used, and, moreover, as squared paper is no longer of service in plotting them, they are not so readily drawn. On the other hand, they possess some undoubted advantages, and polar ruled paper, with a pole in the middle and radial lines from the pole and a succession of thick and thin concentric circles, could very well be manufactured; and though this style of paper would be limited in its use to the delineation of periodic functions, it would probably find a considerable number of grateful patrons. The area of these curves has a simple meaning, the importance of which Dr. Fleming points out in his present article. Moreover, the ordinary sine curve used to represent alternate currents is replaced by a circle in the polar method; that is to say, by a curve whose properties everyone is familiar with. Two sine curves separated by a difference of phase become, on the new system, two circles intersecting at the phase angle. It becomes interesting to consider whether some of the properties of alternate currents, usually demonstrated by means of sine curves, could not be more easily be proved by means of circles. The polar method will probably be even more useful when the currents do not obey a pure sine law, for in such cases averages of squares are dealt with, and, as Dr. Fleming points out, these averages are most readily obtained by inspection of the polar curve.

At the conclusion of his series of lectures on "Alternating and Interrupted Electric Currents," at the Royal Institution, Prof. Forbes showed, in a very beautiful manner, an experiment which, though due to Lord Armstrong, and by no means recent, has been seen by few audiences, and is little known. We refer to the mechanical effect of very high pressure uni-directional currents on a piece of wetted thread or wick connecting two vessels of distilled water. The passage of the current causes the wick or thread to move bodily in the reverse direction to the current, while the water creeps along in the same direction as the current. We have already referred to the original form of this experiment in connection with the changes in the insulation resistance of bare copper conductors, when they are switched into circuit. The form of experiment exhibited by Prof. Forbes is a modification of the original one due, we believe, to Mr. Campbell Swinton. An inner and an outer glass vessel were filled with distilled water, the vessels communicating with one another by a small orifice in

Digitized by Google

the conical bottom of the inner vessel. Some thread was placed in this vessel, and the end of the thread inserted in the orifice. The whole arrangement was projected on a screen. On starting the current from the outer to the inner vessel, the thread was seen to glide at a uniform rate from the orifice, while the convection currents of the inflowing water could clearly be seen in the inner mass of water. When the current was reversed the thread receded into the orifice, and streams of water poured from the orifice into the outer vessel. Perhaps, as Prof. FORBES hinted, there may be the germ of a useful electrical measuring instrument in this very interesting phenomenon. At any rate, some quantitative investigations of it might be made with advantage to pure, if not to applied, science.

AN interesting relation between the currents at various loads, in a synchronous motor, was pointed out by Prof. SILVANUS THOMPSON in the discussion on Mr. W. G. RHODES's Paper at the Physical Society last Friday week. The chief interest lies in a certain resemblance between this relation and the well-known JACOBI's "law" of maximum output of continuous-current motors. JACOBI showed that such a motor is at its maximum rate of working when the back electromotive force cuts the current down to one-half of that which passes when the motor is at rest. Mr. RHODES's development of the fundamental equation for synchronous motors showed, as Prof. THOMPSON observed, that a motor of this type will be generating its maximum power when the current in it is cut down to one-half of that which passes, not when the motor is at rest, but when it is running round idle on frictionless bearings.

THE curious phenomena which a correspondent describes this week, in connection with the glowing of vacuum tubes, has been observed frequently by other experimenters, but we do not remember to have met with an adequate explanation. It is probable, if not almost certain, that the effects are due to the tube acting in some way as a condenser; but it is difficult to see how such small tubes as those in which the effects may readily be produced can have electrostatic capacity enough to give such sharp shocks, or to develop so brilliant an after-glow. The effects are quite distinct from those which are associated with the name of TESLA, and which occur when the tube is placed on a potential gradient in an externally excited field. It is easy to see how the phenomena would be induced under those conditions. But in the instance cited by Mr. W. LOMAS, this week, the tube is assumed to have been removed from the external field, and, though it is evident that the tube acts as a condenser, itself giving rise to the glow which occurs, it is not so easy to understand how apparently so minute a capacity can develop such marked effects. We hope that some of our readers will be able to throw light on what must be regarded as a set of obscure phenomena.

IN commenting on Mr. CROMPTON's recent Paper, on "The Use of Electricity for Cooking and Heating," the *Journal of Gas Lighting* confesses that the heating of water for household purposes, which has proved a rock of offence to electrical heating, "is still the gravest problem to be solved by those who would popularise gas fuel." It is not at first easy to see why the ordinary coal fire gains such an advantage over gas and electric heating in this matter of kitchen boilers, while it is completely beaten by them in all other thermo-domestic work. The fact is simply that the kitchen boiler is a somewhat scientific and efficient affair. This arises from the brick setting in which the boiler is placed, and in a properly arranged kitchen apparatus a very high percentage of the heat of the gases may be made to pass into the water, and the moment anything like a reasonable number of heat units are utilised, electric heating, which has only some 6 per cent. of the total given to it to do the best it can with, becomes, commercially speaking, out of the running.

Light Railways Bill.—This Bill was again down for Second Reading in the House of Commons yesterday.

Personal.—Mr. C. Faraday Proctor has been elected a Member of the Institution of Mechanical Engineers.

Trunk Telephonic Communication in Spain.—The telephone trunk line between Madrid, Saragossa and Barcelona was put in operation on the 26th ult.

Helmholtz Monument.—Committees have been formed in Berlin and Frankfort for the purpose of collecting money for a Helmholtz monument, to be erected at Berlin.

Cable Interruptions:	Date of Interruption.
Latakia—Cyprus	Nov. 27, 1894.
Gibraltar—Tangier	April 24, 1895.

The Researches of M. Melsens.—The students of the late M. Melsens, so well known for his work in connection with lightning conductors, have undertaken the publication of his scientific memoirs.

Electric Traction Bills.—The Earl of Morley's Committee on unopposed Bills has passed the Bill giving an extension of time for the construction of the City and South London Railway from Stockwell to Clapham Common. On Monday last the Dublin United Tramways Bill was read a second time.

Low Temperature Research.—At the General Monthly Meeting of the members of the Royal Institution on Monday afternoon, the special thanks of the members were returned to Mr. George Matthey for his donation of £50 to the fund for the promotion of experimental research at low temperatures.

A Pyrometer Competition.—One of the gold medals being offered this year for competition by the Société Industrielle de Rouen is for an improved pyrometer. The apparatus is to be portable and capable of indicating temperatures of over 300°C. All drawings, designs, &c., are to be sent to the President of the Society before September 2nd next.

Light Railways in Ireland.—In the House of Commons, on Tuesday last, in answer to Mr. Strachey, Sir J. Hibbert said the Acts of 1883, 1889, and 1893 authorised the Treasury to give assistance to light railways and tramways not exceeding a total sum of £65,000 per annum. Of this sum £30,722 was hypothecated to payments for which the Treasury had made itself liable in aid of guaranteed dividends.

Electrically-Propelled Vehicles.—Mr. Naoroji, in the House of Commons, has asked whether the President of the Board of Trade proposed to take steps for allowing vehicles propelled by stored electricity or petroleum, if unobjectionable to the public, to be freely used in this country.—Mr. Shaw-Lefevre, in reply, said he was about to introduce a Bill upon this subject, which he hoped would meet the views of the hon. member.

Obituary.—We regret to announce the death of Mr. Thomas Fuller, who expired at Brighton last Friday, aged 63. Mr. Fuller was Managing Director of the Brazilian Submarine and African Direct Telegraph Companies, and a Director of the West African, the Pacific and European, and the Europe and Azores Telegraph Companies, His loss will be greatly regretted

Digitized by Google

by all who came in contact with him during his long connection with submarine telegraphy.

Société Internationale des Electriciens.—The Council of this Society for the year 1896-97 will be composed as follows:—President: M. Gaston Sciama. Vice-Presidents: M. Léon Violet, M. G. Violle. General Secretary: M. A. Hillairet. Secretaries: M. P. Boucherot, M. Paul Janet. Members: MM. J. Aylmer, Victor Bélugou, Ernest Boistel, Ch. E. Chaperon, Ed. Clémancon, E. Ducrétet, E. Harlé, Ed. Labour, G. Lippmann, E. Marey, H. Ménier, F. Meyer, H. Pellat, Poincaré, J. Sarcia, de la Touanne, Eugène Sartiaux. Finance Committee: MM. Armengaud, jun., A. Berthon, G. Masson.

The Gülcher Arc Lamp.—This day legally expires patent No. 2,038, dated May 10, 1881, which was granted to R. L. Gülcher for "Improvements in Electric Lighting Apparatus." The patent originally embodied two important items; firstly, the well-known Gülcher lamp with its electro-magnet turning on a pivot and attracted by a fixed iron bar; and secondly, a claim for the system of running the lamp in parallel with others. But the invention of the parallel system was disclaimed by the patentee in a formal disclaimer dated October 18, 1882, and an amended specification was published on that date.

American Motormen.—According to the *Electrical Engineer* of New York, a Bill has been introduced in the New Jersey Legislature providing that none but an American citizen over the age of 21 years shall be employed as a motorman in New Jersey. He must undergo an examination as to his fitness before a Board of three motormen selected from among the employés by the superintendent of a road. In order to avoid difficulty in time of strikes, through the refusal of the Board to act, the Bill provides that in such case the Directors of the Company may choose three electricians to examine and license motormen. The Bill also fixes 11 hours, with 45min. for meals, as a day's work for a motorman.

Death from Electric Shock.—A recent accident in the mines of the Leavenworth Coal Company, reported by the *Electrical Engineer* of New York, opens the question as to the possibility of death from a 280-volt shock. One of the labourers was killed, apparently by an electric shock received while handling the machine, notwithstanding the fact that the pressure on the circuit did not exceed this amount. Continued efforts failed to restore animation, although the current was shut off immediately. A post-mortem examination by physicians showed that the heart and brain, and indeed the entire body, was sound, and no marks were present to show the cause of death. The deceased was a strong, well-built man.

Track Bonding.—In a commmunication to the American Institute of Electrical Engineers, Mr. George P. Low, of San Francisco, describes a bonding system devised by F. T. Newberry, a civil engineer of the Pacific coast. It is termed "direct bonding," and the bond consists simply of a copper dowel pin that is shrunken fit into holes drilled into the abutting rail ends. Two or more are used at a joint. The holes are bored just before placing the rails. The ends are heated with a gasoline torch. The dowel pins are driven in the end of one rail, and the abutting rail is forced over the other end of the dowel. With $\frac{5}{16}$in. pins in 70lb. rails, the carrying capacity of two pins would be one-half that of the rail. The bond is protected thoroughly, and its connecting surface is seven times its cross-section. The shrunken fit secured is said to be very tight, and if the bond is not injured by slight lateral movements of the rail ends, it ought to have some advantages.

Electricity in Mills.—At Blies-Schweyen, near Saargemünd, a water-power generating station has been erected for the purpose of supplying current to adjacent works. The plant has a head-water canal of about one mile in length, which supplies about 500 cubic feet per second. The total fall is 13·1ft. There are three turbines of 200 H.P. each, which drive on to a main shaft. From this latter at present two 135-kilowatt "drehstrom" generators of the Oerlikon type are driven by belt, which at 375 revolutions give a potential of 2,900 volts. The exciters are coupled direct to each machine. The first consumer is a paper mill at Ensheim, a distance of about four miles from the power house. Here three 30-kilowatt transformers are employed to transform the current down to 120 volts, driving four motors and lighting the mill.

Brewery Worked by Electricity.—The *Zeitschrift für Elektrotechnik* gives, in its last number, a description of an interesting electrical plant at the Zipfin Brewery, Austria. In the generating station there are four dynamos, two of a total output of 30 kilowatts at 115 volts for lighting, and two of 40 kilowatts at 500 volts for motor driving and the working of an electric railway about one mile in length. This latter connects the brewery with the railway station, and is used for passenger and goods traffic. The average gradient is about 1 in 84. The locomotive, which is fitted with a 15-H.P. motor, draws a train of trucks at a speed of about six miles per hour. Overhead conductors of copper-bronze 8mm. thick are used. The trolley arm had to be placed on a bracket by the side of the locomotive, as doors only 12ft. high have to be passed through.

Mersey Railway Company.—An application was made in the High Court of Justice by the receivers and managers for leave to spend a sum of about £800 in promoting a Bill in Parliament with the object of conferring upon the Company power to work their railway by electricity in lieu of steam. The summons was heard in Chambers, but his Lordship gave judgment on Saturday morning in Court. Mr. Justice Stirling said that the question was whether the money in the hands of the receivers could be thus applied under Section 4 of the Railway Companies Act, 1867. It did not appear to come within "working expenses" of the railway or other proper outgoings in respect of the undertaking. It was an application to Parliament to vary the mode of carrying on the business of the Company. Neither was it in the nature of salvage. If all the parties had been agreed his Lordship might have been inclined to accede to the application. It seemed probable that it might help the business of the Company, but it was a speculation, and his Lordship could not allow any part of the fund in Court to be applied for that purpose.

City and Guilds of London Institute.—The income of this Institute for 1894, not including £275, the amount specially allocated to scholarships by the Clothworkers' and Saddlers' Companies out of their subscriptions, amounted to £33,974, made up as follows:—Subscriptions and donations, £23,767; school fees, &c., 10,207. The total expenditure of the Institute in all its departments has amounted to £30,430. The net amount receivable as fees from students at the Central Technical College was £4,670, the net expenditure on the College being £11,380. The net cost of the College, after deducting students, fees, &c., was £6,709. The net amount receivable as fees from students at the Finsbury Technical College was £3,304, the net expenditure being £9,347, so the net cost of the College was £6,042. The expected income available for general purposes for the year 1895 from contributions amounts to £23,567, from fees, &c., to £9,310, together £32,877; and the Council, on the recommendation of the Executive Committee, have accordingly allotted £32,300 as the provision for the present year. The total amount of the donations and subscriptions to the Institute since its foundation 15 years ago aggregates in round figures to £453,000.

Strassenbahnwagenuntergestelle.—"If," says the *Electrical World* of New York, "any of our readers, in looking over articles on electric railways in the German language, should come across the word *Strassenbahnwagenuntergestelle*, they need not be alarmed or discouraged, nor be afraid to use it in good society. Instead of getting at the subject directly, as is done in English, this single word relates quite a little story—a sort of riddle of which you are expected to guess the answer. The story is, briefly, as follows:—In about the middle of the word we find that the object referred to has some connection with a car, and, returning to the beginning, it appears that this car is intended to run on rails (as cars usually do, by the way), that these rails are in the streets of a city, and that the car is supported on some structure; near the end it is explained that this supporting structure is below, and not above, the car, and, finally, it is added that it refers to the apparatus in general, and not to any one form in particular. With the aid of this description it will not be difficult to guess correctly

Digitized by Google

that the German writer would have said *trucks* instead, had he been privileged to use the English language." It seems to us that this verbal machine is somewhat over-compounded.

Street Subways for Large Towns.—At a meeting of the Society of Engineers, held at the Westminster Palace Hotel on Monday evening, May 6th, a Paper was read by Mr. Charles Mason on "Street Subways for Large Towns." The author, impressing the importance of an improved method of underground construction for the reception of the numerous mains laid beneath the streets, stated that the subject was one requiring the immediate and serious consideration of all engineers to public authorities, gas, water, electric light, and other companies. Further, the difficulties experienced in making periodical examinations of the mains as to leakages and repairs has imposed a duty upon those having the control of the streets to devise some better means whereby the safety of the public is absolutely secured, and the life and cleanliness of the pavements materially benefited. The present system of leaving disused pipes beneath the streets was strongly condemned. The author, in explaining the construction and uses of existing subways both in the provinces and the metropolis, pointed out the chief difficulties in the way of their general adoption as being the question of light and ventilation, and cost of construction; also in his opinion, the "single" system was open to objection, as the mains having to be placed on one side of the subway, compel the supply pipes to be taken across the same for supplying premises on the opposite side of the street, thus blocking the passage way and causing obstructions in the flow of the pipes themselves; the difficulties of sewer ventilation were also referred to. The author proposed "triple" subways having a central avenue for trunk mains, and side avenues for subsidiary or service pipes, vaults being provided beneath the footways remaining the property of the public authority and leased to the adjoining owner, thus providing some return for the outlay.

Research in Education.—In a recent number of *Nature*, Mr. D. S. T. Grant, of the Chemical Laboratory, Lahore, Punjab, delivers himself of the following interesting criticism:—

"Prof. Armstrong's trenchant indictment of the present methods of teaching science is a little too much akin to Carlyle's fulminations against things in general—destructive but not constructive. Probably all good teachers are agreed upon the pernicious futility of the text-book and lecture room cram system, and are in thorough accord as to the educational value of practical work; and are waiting only to learn or discover the best system of employing it. To this end destructive criticism helps but little. What is wanted is some definite scheme of work constructed by masters of practical instruction. Prof. Armstrong does certainly advocate what may be termed the 'research method'; but it does not elucidate the question much, for it is difficult to understand how far he would extend this method. Would he, for instance, never mention Dalton's laws to students until, by a series of analyses, they were in a position to discover them for themselves? Or in the case of specific heat, how much information should be given before the beginners are set to investigate the phenomena alone? There are two ways of learning practically physical and chemical truths, either by repeating methods which have been explained and demonstrated, and then verifying each step by actual contact with real objects, and so acquiring real knowledge of fact and the application of theory, or by struggling to the truth by a process of trial and error. That the latter process, when successful, is the more stimulating to the intellect may be admitted, but that it is practically possible must be doubted. In introducing any new subject to the mind, surely broad outlines should be given first, and details filled in afterwards; observation requires teaching as much as any other faculty. Tyndall tells this story of Faraday. As Tyndall was about to show the latter an experiment, Faraday laid his hand on his shoulder, and said, 'Wait a minute; what am I to look for?' The application is plain—even Faraday felt the advantage of having the observer fore-armed. Beginners know not what to observe, and cannot fashion experiments for themselves, and therefore it seems more rational that students should have the recognised methods of science explained and demonstrated to them, and then be caused to repeat the necessary operations practically, numerical details being varied as in mathematical exercises. When thus equipped with sound theoretical knowledge and fair manipulative dexterity, they will be in a position to embark upon 'research'; for they will then have acquired some power of observation, accuracy, and the faculty of making inferences. The 'research method' *ab initio* appears like an attempt to teach a child to read before he knows his letters. I am fully conscious of my audacity in venturing into the lists, and am not ignorant of the sort of folk who 'madly rush where angels fear to tread'; but if I can elicit some definite scheme from Prof. Armstrong, I shall regard my own dialectic annihilation as a small price to pay for the ultimate gain."

An American Two-Phase Station.—It is now about a year ago that the station of the Brush Electric Company, of Baltimore, was almost entirely destroyed by fire. The officers of the Company made temporary arrangements to supply their customers and the city lights with current, and at the same time set to work planning a new station. The new station consists of a one-storey building, with substantial brick walls. The roof is one span, without columns, 30ft. to the underside of truss, and 65ft. high at its peak. The roof is of iron, and lined with fireproof material. The floor is granolithic. The only woodwork about the building is to be found in the doors and window frames. Beneath the floor of the station there are a series of brick passages, two of which are arranged to carry the exhaust steam, water, and drain pipes, and two others to carry the large cables from the dynamos to the switchboards. The station is arranged for four two-phase Westinghouse alternating machines, each having a capacity of 15,000 16-candle lights. They are direct-coupled to vertical double-acting Westinghouse compound engines. Each engine and dynamo weighs 139 tons, the armatures alone weighing 20½ tons. The engines are placed on brick foundations. It is the intention of the Company to run eventually all the arc lights and motors on the two-phase circuits, using the Tesla two-phase motors. The present arc-light equipment of the station consists of 18 65-light machines of the Brush type, and five 80-light machines of the Westinghouse type. The machines are belted to vertical Westinghouse compound engines. The boiler house contains a large tank for the storage of coal, capable of holding 1,500 tons. There are five vertical Climax water-tube boilers of 500 nominal horse-power capacity each, with space for three more boilers of this type. In addition to this, there are two batteries of horizontal tubular boilers, four in each battery. These are not now in regular use, but are retained for occasions of emergency. The Company contemplates replacing them shortly with horizontal water-tube boilers. Arrangements are now being completed for the introduction of coal-handling apparatus and mechanical stokers. Soft coal mixed with anthracite screenings is used, and from 50 to 75 tons a day is consumed. The smoke from the boilers is carried off by two stacks, each 150ft. high.

Electric Traction Proposed for the Leeds Municipal Tramways.—The report of the Tramways Committee of the Leeds Corporation, setting forth their investigation into tramway traction and their recommendations in the matter, has now been prepared, and will shortly be presented to the Highways Committee for approval. The existing system aggregates 27 miles of track, and when the proposed extensions are carried out the total will be over 41 miles. The total capital expenditure on the lines already in existence is £143,617. The Committee have come to the conclusion that the present dual system of haulage, viz., by steam and horse-power, should be superseded; that oil, gas, and compressed air are at present impracticable; and that having regard to the many different routes in Leeds and the total length thereof, the varying requirements of each route as to frequency of service, and the fact that the steep gradients are here uncommon, they are unanimously of opinion and recommend to the Highways Committee that electric traction is the most suitable for the tramways of the city, and, on the whole, the Committee's preference is for electric traction with overhead wires, except in the centre of the city, where a conduit system should be adopted. The city accountant has submitted to the Highways Committee a balance sheet showing the result of the working of the tramways. The undertaking was handed over to the Corporation by the old Company on February 2, 1894. During the year ended March 25th last, the total income was £51,013. 10s. 7d., and the expenditure £44,123. 8s. 11d., leaving a gross profit of £6,890 1s. 8d. From that has to be deducted the interest and sinking fund charges, which amounted to £6,756. 14s. 3d., so that there is an actual surplus on the year's working of £133. 7s. 5d. Since the tramways came under the control of the city, the Committee have had to meet heavy exceptional expenditure out of revenue. Then, again, the Committee have reduced the number of hours worked by the employés, and have increased their wages. During the period covered by the accounts the Corporation have carried over 1¼ million more passengers than the late Company ever did in a similar time, while the mileage run has been increased by over 160,000.

ELECTROMAGNETIC THEORY.—LXVIII.*

BY OLIVER HEAVISIDE.

(Continued from page 786, Vol. XXXIV.)

§ 264. Having accumulated a stock of formulæ in the last few sections, it becomes necessary to explain their connection with Fourier series. Given an electromagnetic operational equation, say $e = ZC$. Here C is some particular effect due to a cause e, as, for instance, the current in one part of an electrical system due to an impressed force in another part, though it is not necessary to restrict their meanings in this way. The operator Z is to be constructed in the way previously explained in § 244 (or in any equivalent way), that is, in the same way as if the elements of the combination were mere resistances subject to Ohm's law, to be generalised in the final result to the functions of p, the time differentiator, which are appropriate to the real nature of the elements.

Some ways of algebrising such operational equations have been already given, especially applicable to diffusion problems, though they have a wider application. One way in particular should be noted and remembered, namely, the resolution of the operator Z by algebraical division into wave operators. This is a very simple and powerful method, which applies very generally in physical problems concerning continuous media. The effect is to express the solution in the form of the sum of a series of waves. These may be either simultaneous or successive, according to circumstances. There may be but one wave, or two, or an infinite number. If the method had no other recommendation, it would have this important one—that in considering the effect due to a source it imitates nature by directly expressing the course of events in the way it happens in actual fact, whereas an alternative and equivalent formula might completely disguise it.

But there is another very different way of resolving an operator into other more elementary ones, which leads to a strikingly different functional expression of the developed solution. The results are so entirely unlike the wave results that their equivalence produces algebraical identities which are rather astonishing at first. Only by the familiarity with them, which their universal existence in physical problems involving propagation (subject to certain restrictions) makes possible, do they become commonplace. We may express our results either in terms of the waves or in terms of the vibrations of normal systems of disturbances. Or, in the latter case, if the vibrations be frictionally resisted, in terms of the subsidences or decadences of the normal systems. We may compare the two developments to the branches and the roots of a tree. They are widely separated, but have a common bond in the trunk which joins them. The trunk corresponds, of course, to the operational solution. No doubt the analogy will fail if pushed much further. A perfect analogy in every respect would require an identity, for nothing is wholly like anything but itself, and an identity would be useless for an analogy. The present one is good enough as far as it goes here.

It is not a matter of indifference which way of development is employed. It may be that in some particular problem one of the two is far more manageable than the other, or more amenable to numerical calculation. Apart from this, it depends upon circumstances which of the two ways is to be preferred by its natural recommendations. Take, for instance, the case of a long stretched cord, fixed at its ends. If we disturb it so as to make a hump or a number of humps run along the string, that is, if we produce evident and visible progressive waves, it is natural to express the mathematical results in the form of waves. Again, if we displace the whole cord to the form of a sine curve, and let it go, it will vibrate in the same form over and over again, whether the sine curve be only half a complete wave length, or have intermediate nodes. Here it is obviously natural to express mathematically the visibly evident simple vibrations as vibrations simply.

But in the former case the progressive wave may be expressed entirely in the form of normal vibrations, and in the latter the vibrations may be expressed entirely in the form of progressive waves. The methods are perfectly equivalent quantitatively. We see at once, however, that it is not natural to express the simple progressive wave in the form of normal vibrations, or the normal vibration in the form of progressive waves, because the results would disguise the reality. The examples used here are extreme. In intermediate cases it may be quite difficult to say which way is preferable, owing to both ways being complicated. There may, however, be numerical advantage in using one form; or, more likely, one form may be useful in one part of the history of events, and the other form later, of which there are many examples in diffusion problems. The normal vibrations may involve much labour in calculation for some particular value of the time, when, under the same circumstances, the waves are easily done; and conversely.

We should remark, however, that in pure diffusion problems we are not concerned with true vibrations, as of a string. The resistance stops the vibrations, so the disturbances simply subside or decay. Thus, if the potential in a submarine cable, imagined to be quite free from self-induction, be distributed according to a sine curve, say $V = V_0 \sin ax$, with nodes at beginning and end, if earthed terminally, and be left to itself, the curve of potential will preserve its sine form, though continuously falling to equilibrium. But self-induction will make it pass through the equilibrium position, and the potential will vibrate, though decaying at the same time. This is oscillatory subsidence. By reducing the resistance, or increasing the self-induction, or in both ways together, we make the vibrations last longer, and resemble those of a stretched cord. The limit would be reached if there were no resistance. The vibrations would continue for ever, without loss of intensity, like those of the string in acoustical theory, when friction is ignored. The stretched cord makes by far the best analogy for a telegraph circuit when it is desired to have a simple analogy, because every one knows something about how a cord vibrates, and how pulses are transmitted along it, and reflected, and so on until finally killed by friction. They are visibly evident. Now all these things have their close representatives in a telegraph circuit, which makes the simple analogy be very useful. Of course, it is an entirely different matter when the etherial theory is in question; then suitable analogies are of a different nature, which may, perhaps, be as difficult to follow as the electromagnetic theory itself, as, for instance, the continuous medium first imagined by MacCullagh, in which rotational elasticity is involved. In one respect, however, the stretched cord fails. It does not, at least in any simple manner, represent the effect of leakage on a telegraph circuit. Prof. Fitzgerald, however, by employing the vibrations of air in a pipe in the analogy, was able to include leakage. But the pipe analogy is not so easily followed in most respects as the stretched cord, since compressions and condensations of the air are less easily pictured than the motions of a cord.

In speaking of the diverse modes of representation as being in terms of waves and of vibrations, of course progressive waves are referred to, whether undistorted or distorted as they progress. Progression is the essence of a wave. "Standing" waves are somewhat deceptively so called, if simple normal vibrations be included therein. Now the reader must be cautioned against supposing that every operational equation is convertible, as described, into waves or normal vibrations. Some operational equations refuse to go more than one way, save perhaps by artificial expedients. They make waves only, or vibrations only, but not both. Why these failures occur is evident in practice by physical considerations. Mathematically, it is due to peculiarities in the form of the Z operator. As an example of waves only, there can be at most only two waves from one source situated in an infinitely long cable, as in § 255. Then we cannot have a vibrational form of solution (if we include subsiding normal systems under vibrations), except artificially. And, of course, when there is only a limited number of degrees of freedom in an electrical arrangement, as in the theory of condensers and coils, we have vibrations or vibrational subsidences or pure subsidences of normal systems in limited number which do not admit of

* This series of articles is a portion of Vol. II. of Mr. Heaviside's work on "Electromagnetic Theory." All rights of reproduction are reserved.

Digitized by Google

expression in the form of continuous waves, except perhaps very artificially. Generally speaking we may have both, when there is a continuous medium for propagation in some part of the system. The distinction is usually connected with the presence or absence of boundaries. If we create a disturbance in an elastic medium which is quite homogeneous and is unbounded, the disturbance goes out to infinity in wave fashion, and no free vibrations in definite and separate modes are possible. But if the medium is bounded, the wave cannot dissipate itself freely, but is reflected and re-reflected any number of times. We can now express the disturbance in terms of the vibrations of definite normal systems of a complicated nature, depending upon the nature of the medium and on the form, &c., of the boundary. The possibility arises from the superposition of an infinite number of progressive waves, and we may express our results either in terms of waves or of vibrations.

This brings us to the reservation made about an artificial way of representing a progressive wave by vibrations. If in the last case we imagine the boundary shifted further and further away, however far we go the normal systems remain distinct and separate, and the two modes of representation are in force. Now, in the limit, when the boundary is removed to an infinite distance, the expression for the sum of the normal systems becomes a definite integral. Thus a single progressive wave may be expressed by a definite integral as the sum of vibrations of infinitely numerous normal systems differing infinitely little from one to the next. Instead of a definite sequence of separated periods, the periods run into one another. Of course it is simpler to think of the progressive wave than of the definite integral which equivalently expresses it, though not in a desirable manner, and to derive it directly from the operational solution when possible, instead of through the integral.

After these general remarks about the chief peculiarities, we must proceed to show practical methods of manipulating the Z operator so as to convert operational solutions to vibrating or subsiding normal systems. It is not difficult by the general method to be explained. Perhaps it is too easy. That is, too easy in execution, for the theory thereof is more difficult. As, however, it applies to all sorts of normal systems besides those concerned in Fourier series, it will perhaps be best to show the connection of Fourier series with the operational forms in more special ways, which, though longer, may be more immediately intelligible to the unpractised in operational methods.

§ 265. Take, to begin with, an interesting special case, namely, the effect due to steady impressed force e at A, where $x=0$, when earth is on at both A and B, where $x=l$. As before shown, the operational solution is

$$V=\frac{\text{shin}\, q(l-x)}{\text{shin}\, ql}e. \tag{1}$$

The conversion to a Fourier series in this and many other simple cases can be done by using well-known trigonometrical identities, assisted by an elementary operational result. Thus, we have

$$\frac{ql}{\text{shin}\, ql}=1-\frac{2}{1+\left(\frac{\pi}{ql}\right)^2}+\frac{2}{1+\left(\frac{2\pi}{ql}\right)^2}-\frac{2}{1+\left(\frac{3\pi}{ql}\right)^2}+\dots, \tag{2}$$

by trigonometry. Here noting that q^2 means RSp, we see that we have merely to algebrize $(1+P/p)^{-1}1$, where P is a constant. Thus, in full,

$$\frac{1}{1+\frac{P}{p}}=1-\frac{P}{p}+\left(\frac{P}{p}\right)^2-\left(\frac{P}{p}\right)^3+\dots=1-Pt+\frac{(Pt)^2}{\lfloor 2}-\frac{(Pt)^3}{\lfloor 3}+\dots;$$

or, in the usual brief expression of the exponential function,

$$\frac{1}{1+\frac{P}{p}}=\epsilon^{-Pt}. \tag{3}$$

This result should be noted, as it often turns up. Applying it to (2), we obtain

$$\frac{ql}{\text{shin}\, ql}e=e\{1-2\epsilon^{p_1t}+2\epsilon^{p_2t}-2\epsilon^{p_3t}+\dots\}, \tag{4}$$

where the constants p_1, p_2, &c., are given by

$$p_n=-n^2\pi^2/RSl^2. \tag{5}$$

Comparing (1) with (4), we see that V will be found by operating on (4) by

$$\frac{\text{shin}\, q(l-x)}{ql}. \tag{6}$$

This is a function of q^2 also, so involves only complete differentiations. They may be carried out at length if desired, but that is unnecessary. For the power of p in the operator (6) on ϵ^{Pt} is simply P. It is therefore zero on the first constant term on the right of (4), then p_1 on the second term, and so on. That is, these values are to be put in (6) for p to express its effect. So (1) is converted to

$$V=e\left(1-\frac{x}{l}\right)-2\frac{\text{shin}\, q_1(l-x)}{q_1l}\epsilon^{p_1t}+2\frac{\text{shin}\, q_2(l-x)}{q_2l}\epsilon^{p_2t}-\dots, \tag{7}$$

where the q's are the constant values corresponding to the p's, through $q^2=RSp$. Equation (7) is the full solution, but for trigonometrical convenience, since the values of q^2 are negative, it is best to put $q^2=-s^2$. This makes

$$V=e\left(1-\frac{x}{l}\right)-2\frac{\sin s_1(l-x)}{s_1l}\epsilon^{p_1t}+2\frac{\sin s_2(l-x)}{s_2l}\epsilon^{p_2t}-\dots; \tag{8}$$

or, since $\sin sl=0$ for every s,

$$V=e\left(1-\frac{x}{l}\right)-\left(2\frac{\sin s_1x}{s_1l}\epsilon^{p_1t}+2\frac{\sin s_2x}{s_2l}\epsilon^{p_2t}+\dots\right), \tag{9}$$

where the s's are the roots of $\sin sl=0$, which is the same as saying that the p's are the roots of $\text{shin}\, ql=0$. In the customary form (9) is the same as

$$V=e\left(1-\frac{x}{l}\right)-\frac{2e}{\pi}\Sigma_1^\infty\frac{1}{n}\sin\frac{n\pi x}{l}\epsilon^{-n^2\pi^2t/RSl^2}. \tag{10}$$

This is the equivalent of the wave solution before got.

When $t=\infty$, the time factors vanish, and there is left the final state expressed by the outside term. On the other hand, when $t=0$, the time factors are unity, and

$$V=e\left(1-\frac{x}{l}\right)-\frac{2e}{\pi}\Sigma_1^\infty\frac{1}{n}\sin\frac{n\pi x}{l}. \tag{11}$$

We know that V is initially zero everywhere except at A, where it is e. Therefore

$$1-\frac{x}{l}=\frac{2}{\pi}\Sigma_1^\infty\frac{1}{n}\sin\frac{n\pi x}{l}, \tag{12}$$

except at $x=0$, where the right member gives zero. That is, the steady state, which is $e(1-x/l)$, has become expanded in a series of sines. But we have got more than we wanted. For the Fourier series is periodic, with period $2l$. So the right member represents $1-x/l$ between 0 and $2l$; then the same values are repeated from $2l$ to $4l$; and so on. Similarly on the left side of the origin. Equation (11) is, in fact, the solution of the problem of finding V due to an infinite number of equal impressed forces of strength $2e$ acting all the same way at the points 0, $2l$, $4l$, &c., $-2l$, $-4l$, &c., in an infinitely long cable. This was shown before as regards the operational and wave solutions.

§ 266. There is another similar way of getting (9) which is worth noticing. Use the trigonometrical identity

$$ql\coth ql=1+\frac{2}{1+\left(\frac{\pi}{ql}\right)^2}+\frac{2}{1+\left(\frac{2\pi}{ql}\right)^2}+\frac{2}{1+\left(\frac{3\pi}{ql}\right)^2}+\dots, \tag{13}$$

differing from (2) on the right side only in the signs of the terms. Let the operand, as before, be 1 in the usual manner, and we obtain

$$ql\coth ql\,.\,e=e(1+2\epsilon^{p_1t}+2\epsilon^{p_2t}+2\epsilon^{p_3t}+\dots), \tag{14}$$

instead of (4) above, with the same values of the p's.

Now (1) is the same as

$$V=(\cosh qx-\cosh ql\,\text{shin}\, qx)e$$

$$=\cosh qx\,.\,e-\frac{\text{shin}\, qx}{ql}e(1+2\epsilon^{p_1t}+2\epsilon^{p_2t}+\dots), \tag{15}$$

Digitized by Google

by (14). Here the power of p is zero in the cosh function, and also in the other so far as the constant term goes, and p_1 on ϵ^{pt}, &c. So, putting $q^2 = -s^2$, we get

$$V = e\left(1 - \frac{x}{l}\right) - 2e\Sigma\frac{\sin sx}{sl}\epsilon^{pt}, \qquad (16)$$

which is the same as (9).

Since circular functions are finally to be employed, we may put $q^2 = -s^2$ at the beginning if we like, and write

$$V = \frac{\sin s(l-x)}{\sin sl}e, \qquad (17)$$

instead of (1). Here of course s^2 is a differentiator, namely, $-RSp$. It finally takes the meaning of a constant, or rather of an infinite series of constants, merely because p has the power of a constant on the exponential function.

The determinantal equation shin $ql = 0$, or, more strictly, (shin $ql)/ql = 0$, is really the equation finding the admissible values of p in the normal systems. To every p belongs an s^2, so if we choose to consider the determinantal equation in the form (sin $sl)/sl = 0$ as finding the values of s, we need only attend to the positive values.

Notice also that the operator in (1) does not contain $p^{\frac{1}{2}}$, but only the complete p. The elementary waves which make up the solution (1) do depend on $p^{\frac{1}{2}}l$, but the union of all the wave operators to make the solution (1) causes $p^{\frac{1}{2}}$ to be eliminated. The determinantal equation for a cable of finite length—that is, bounded both ways by some restraint, is always a rational equation in p, provided the terminal arrangements themselves are finite combinations whose resistance operators are themselves rational functions of p.

(To be continued.)

REPRESENTATION OF PERIODIC CURRENTS BY POLAR DIAGRAMS.

BY DR. J. A. FLEMING, F.R.S.

Two methods of graphically representing simple periodic currents or electromotive forces, viz., clock diagrams and wave diagrams, are in constant use. Each of these methods has some peculiar advantages of its own. There is, however, a third method which has sometimes especial utility, and this is by a polar diagram.

Let a straight line O P (Fig. 1) revolve round one of its extremities O, and let the angle of inclination θ which the revolving line makes with another fixed straight line O A, passing through this centre of revolution be called the angle of displacement of the revolving line. Let any point P be taken on the revolving line, and let the distance of this point from the centre be denoted by r. The length r is called the radius vector. Let r increase or diminish as O P revolves, but so that the length $OP = r$ varies according to any law connecting it with the angle of displacement A O P. The extremity P of the line O P will then trace out a curve called a polar diagram.

Suppose that O P runs through a cycle of values beginning with a zero value when $\theta = 0$, and after reaching a maximum value becoming zero again after the line O P has completed one half revolution, or when $\theta = \pi$, the polar diagram will be a closed curve passing through the origin. Since the radius O P runs through a cycle of values from zero to a maximum, and returns to zero again during a revolution of the radius through two right angles, or an angle π, the radius r may suitably represent the value of any periodic quantity which completes a cycle of values in the time represented by one complete half revolution of the radius vector. Suppose, then, that O P varies as sin θ where θ is the displacement phase angle—that is, let

$$r = R \sin \theta,$$

it is then clear that in this case the polar curve is a circle. For if we draw the line O B through O perpendicular to O A, and draw P B at right angles to O P, since $AOP = \theta$ and $OP = r$, and since by supposition $r = R \sin \theta$, it follows that the angle P B O is always equal to θ, and then, therefore, the length O B is a constant length equal to R. In other words, the *locus* of the point P is a circle passing through O, P, and B. Hence the circle is the curve which represents in a polar diagram a simple periodic quantity, and if the length O P is taken to represent the magnitude of a simple periodic current or electromotive force at any instant corresponding to a phase angle A O P, the circle passing through O will be the polar curve representing this simple periodic current or electromotive force.

If the current or electromotive force is periodic, but not simply periodic, then the polar curve representing it will be a unicursal curve passing through the origin O, but will not be a circle. The polar diagram of an alternating current or electromotive force enables us very easily to determine the

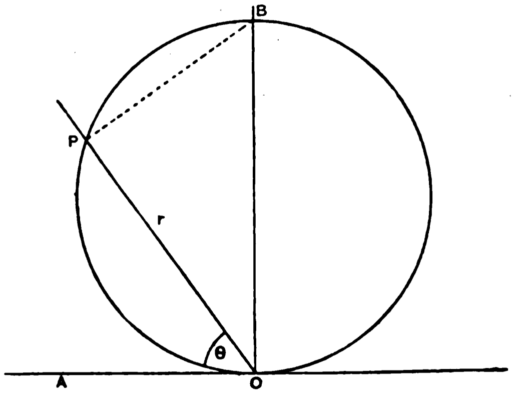

FIG. 1.

square root of the mean-square value of the periodic quantity represented by it. It is more difficult to do this with the ordinary wave-curve diagram.

Suppose, for example, that in Fig. 2 we have a wave diagram drawn representing a half wave of an alternating electromotive force which is not a simple sine curve. The ordinates represented by the dotted lines are proportional to the instantaneous values of the periodic quantity taken every 20deg. If we wish to find the $\sqrt{\text{mean}^2}$ value of the ordinates of this curve there is no other way of doing this than by drawing a number of numerous equidistant vertical ordinates, measuring their lengths, squaring these magnitudes,

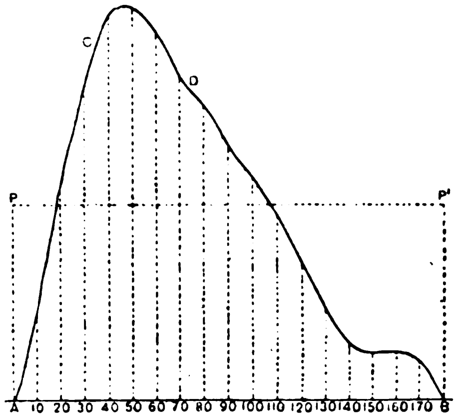

FIG. 2.

and taking the square root of the mean of these squares. This is a troublesome arithmetic process, and in proportion as the wave curve is more irregular or complex, so much the more numerous must be the ordinates to obtain a correct result for the mean-square value. It is, however, a much easier process if the periodic quantity is represented by a polar curve. Let Fig. 3 represent the same periodic function as in Fig. 2 drawn in a polar form. The dotted radii are proportional to the instantaneous values of the periodic quantity, and are placed at angular intervals of 20deg. Let any radius O P (*see* Figs. 3 and 4) be denoted by r, and let the corresponding phase angle P O A be denoted by the letter θ. If we consider the radius to move forward by a small angle $d\theta$ and to increase

Digitized by Google

in length by a small amount dr, then it is obvious that the small increment of area dA swept out by the radius r is equal to $\frac{1}{2} r^2 d\theta$. To obtain the whole area, and included by the polar curve O P Q R, we have to integrate this quantity $\frac{1}{2} r^2 d\theta$ from 0 to π, or to obtain the integral

$$A = \frac{1}{2}\int_0^\pi r^2\, d\theta.$$

On the base line drawn through the polar centre O let a semicircle A C B (*see* Fig. 3) be described equal in area to the area included by the polar curve O P Q. Let O A = R be the radius of this semicircle. Then

$$\frac{\pi R^2}{2} = A = \frac{1}{2}\int_0^\pi r^2\, d\theta,$$

or

$$R = \sqrt{\frac{1}{\pi}\int_0^\pi r^2\, d\theta}.$$

The expression on the right hand side of this last equation is obviously the square root of the mean of the squares of the

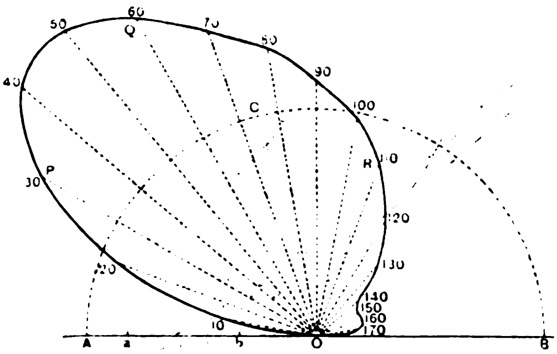

Fig. 3.

instantaneous values of the periodic quantity r. Hence, we can obtain at once the $\sqrt{\text{mean}^2}$ value of a periodic quantity current or electromotive force as follows. On any straight line describe a semicircle and draw radii of this semicircle at angular intervals equal to those phase intervals for which the instantaneous values of the current or electromotive force are observed. Set off on these radii lengths equal to the respective values of these instantaneous quantities and join the extremities of all these lines so set off by a curve. This curve

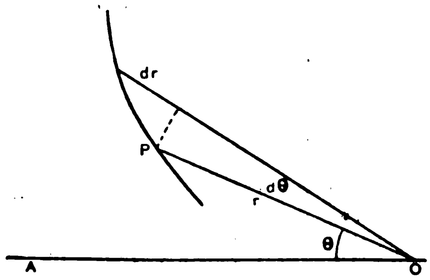

Fig. 4.

is the polar diagram, and it is a closed curve. Take the area included by the polar diagram with an Amsler's or other planimeter, and from a table of areas of circles find the circle whose area is double that of the polar curve. Then the radius of this circle is the square root of the mean of the squares of the periodic quantity. If, for instance, we have a periodic current curve plotted down in polar form this operation will give us the dynamometer value of the current, or the value which would be read on a dynamometer.

The polar curve, therefore, lends itself very easily to the determination of the mean-square value of a periodic current or electromotive force, of which the instantaneous values are known throughout a semi-period, whether those values are taken at equidistant intervals of time or not. The reader will, therefore, note that if we plot down a periodic quantity in rectangular co-ordinates (Fig. 2) or *wave form*, and find the rectangle A P P′ B of equivalent area to the half wave, the altitude A P of this rectangle gives us the *true mean ordinate* of the periodic curve; but if we plot down the periodic quantity to a *polar diagram* (Fig. 3) and find the semicircle A C B of equivalent area, the radius O A of this semicircle gives us the *square root of the mean-square value* of the periodic quantity represented by the radii of the polar curve.

SHEFFIELD ELECTRIC SUPPLY STATION.

Until the commencement of the present year, when the new extension plant was put in operation, the generating station of the Sheffield Electric Light and Power Company suffered from a condition—highly desirable in moderation—of having abundance of work to do. It was smitten with that disease for which the mathematical diagnosis is, that the rate of increase in the demand for light was far in excess of the utmost possible increase in the rate of meeting that demand. Consequently, at times of highest load, there was not only no reserve plant, but the working plant was taxed to its utmost limits. That anxious moments and bad quarters-of-an-hour should result was only to be expected. We are sure that there are many stations in this country where the managers would wish to see their surplus

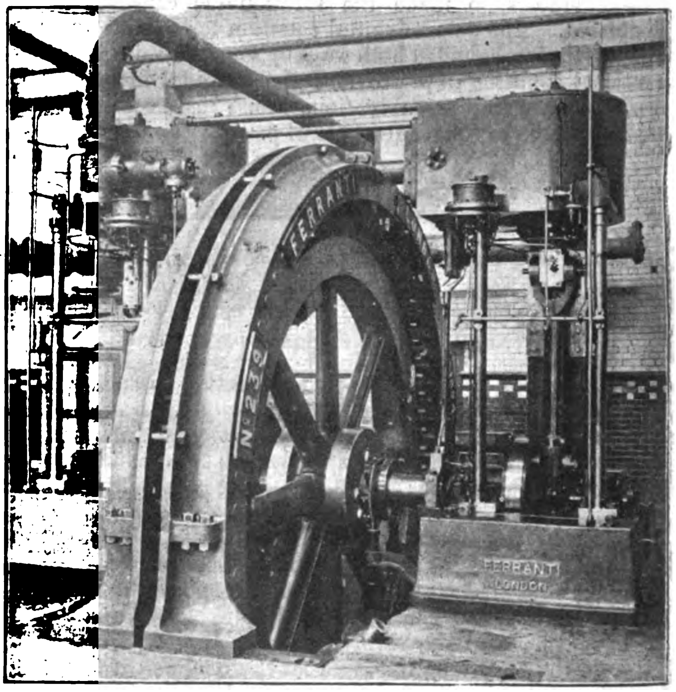

Fig. 3.—Sheffield Electric Supply Station. Extension Plant.

plant less persistently idle than is actually the case; but there are few, if any, who would care to run such a close shave as there was at Sheffield before the extension took place. Differences of opinion, as well as differences of fact, exist in regard to surplus plant. Some of the Sheffield customers thought there ought to be 100 per cent. of reserve; on the banking principle, we suppose, of holding cash reserve equivalent to circulated paper! But the directors of the Sheffield Electric Light Company do not see their way to such a luxury, though they do expect in future to keep a reserve of not less than 20 per cent. At present the extension plant is capable of taking over the entire normal load of the original plant; that is to say, while the total capacity of the four older machines is only 285 kilowatts, the single new machine has a capacity of 300 kilowatts.

The lighting at Sheffield is arranged on the high-pressure alternating-current transformer system, the original contract for the electrical plant being carried out by the Brush Company. Figs. 1 and 2 show this plant from opposite ends of the spacious bay which forms one-half of the large and well-constructed machinery hall. There are two bays, but one of these is at present entirely unoccupied by machinery. The plant shown in these illustrations comprises two 100-kilowatt, one 50-kilo-

Digitized by Google

watt, and one 35-kilowatt Brush alternators and steam engine. These were at first rope-geared on the usual Brush plan, using only one rope for each machine. But the failure of a set through the parting of the rope one busy Saturday night, led the engineer to abandon this arrangement in favour of the safer practice of driving with several independent ropes.

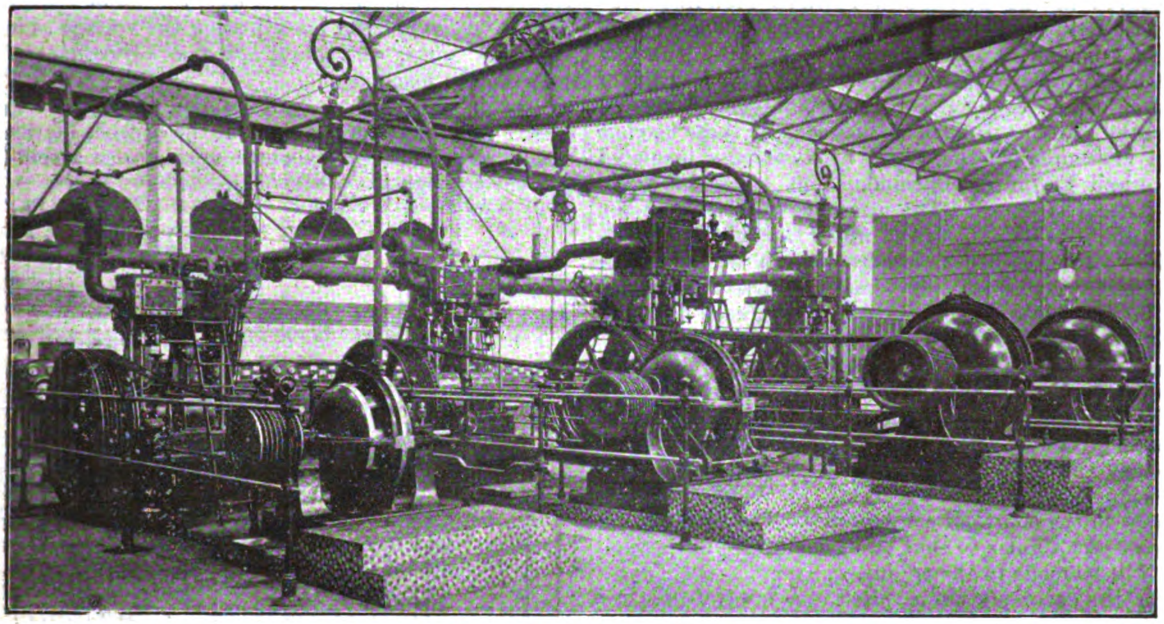

Fig. 1.—Sheffield Electric Supply Station, showing original Generating Plant. Space for extension in far corner.

The extension plant has been built by Messrs. S. Z. de Ferranti and Co.; the steam engine, which is coupled direct to the flywheel alternator, having been sub-contracted for by Messrs. Browett, Lindley and Co. A view of this plant is given in Fig. 3, the splash-guards having been removed to show the working parts.

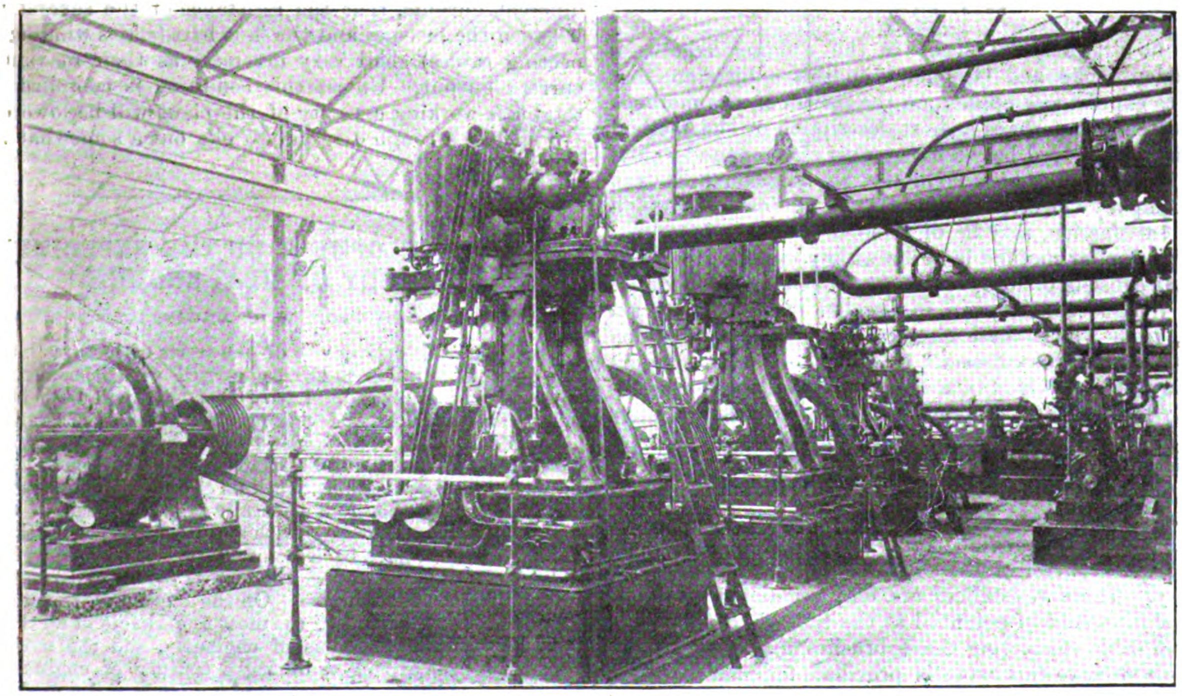

Fig. 2.—Sheffield Electric Supply Station. View from site of Extension Plant.

This steam plant consists of a high and low-pressure engine placed one at each end of the alternator shaft, the main bearings of the engine also serving as the alternator bearings. There are thus only two main bearings in the whole machine, and, as these are constructed on Mr. Ferranti's spherical system, no trouble can occur from their being out of line. The high-pressure engine has a cylinder 19½in. in diameter and a stroke of 20in., the cylinder being supported on a massive cast-iron standard at back, and on two stiff turned steel stays in front. A piston valve is used, actuated by an eccentric on the shaft, a shaft governor being used to control the speed by varying the cut-off. The low-pressure engine has a cylinder 32½in. in diameter by 20in. stroke, and is fitted with a double-ported Trick slide valve, also driven by means of an eccentric on the engine shaft. Very liberal strengths are allowed all through, and complete provision for copious oiling and prevention of oil splash or waste has been made. The crank pins are fitted with spherically-seated brasses, and are oiled on Lindley's patent system. The crank discs are of cast steel. Oil is supplied under pressure to the main bearings, and other bearings are fed from a large oil box in front of the engine with an adjustable oil supply to each. The engine is fitted with sight-

Digitized by Google

feed lubricator relief valves, and everything requisite to ensure satisfactory and efficient running. The alternator is designed to run in parallel with the original plant, at a frequency of 100 ∿.

On the rim of the flywheel is mounted the armature of the Ferranti alternator, which consists of 40 pairs of bobbins of an improved construction, but similar in principle to that always employed in the well-known Ferranti high-frequency dynamo. The design allows very great rigidity. The bobbins are wound on a laminated brass core, with alternate layers of corrugated copper ribbon and white fibre. Each pair of bobbins, after being connected together, is solidly riveted into two heavy gun-metal carriers, and each of these carriers or brackets is secured to the wheel by two bolts, insulated with ebonite and Ferranti compound. This gives the armature great lateral strength. The armature revolves between two massive cast-iron frames, each of which supports 80 electro-magnets, the weight of each complete frame being 5½ tons. The frames themselves consist of heavy castings, in each of which are placed 80 wrought-iron cores, or pole pieces, each fitting in an accurately-machined 3½in. hole. On each of these cores is placed a field magnet coil, consisting of copper tape wound on edge, according to Messrs. Ferranti's latest design, which, while allowing the greatest amount of copper to be placed in the smallest space, gives very efficient insulation and large radiating surface, and at the same time gives a handsome appearance to the machine. A new 300-kilowatt plant by the same makers is now in the course of construction. The dynamo will be in every respect similar to that lately installed; but several alterations will be made in the engine.

Steam for the entire station is raised in five water-tube and two Lancashire boilers, of an aggregate capacity of 2,000 H.P.

Our thanks are due to Mr. W. Johnson, the manager and secretary of the Sheffield Electric Light and Power Company, and to Messrs. S. Z. de Ferranti and Co., for their kindness in supplying us with the information and illustrations for this article.

PARALLEL RUNNING OF COMPOUND-WOUND MACHINES.

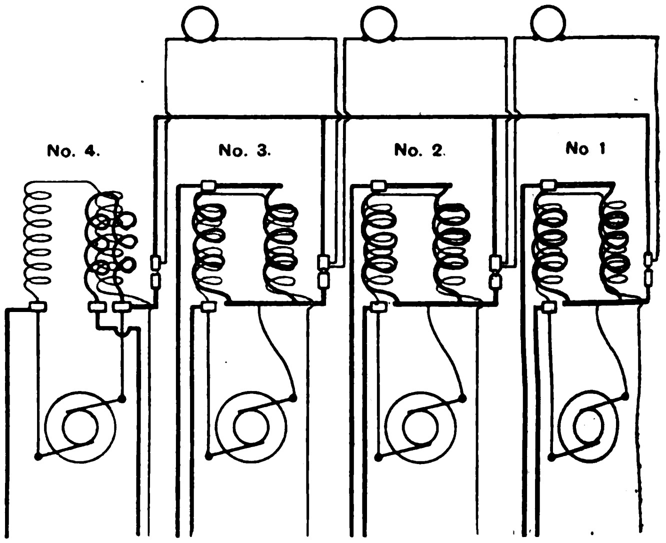
BY J. PIGG.

I have no desire to intervene in the discussion between Messrs. Addenbrooke and Goodchild on this subject, neither do I wish to express any opinion on the merits of the methods they advocate; but perhaps a short description of the method for apportioning the load between a number of compound-wound machines in parallel, which is in use at the North-Eastern Railway Company's electric lighting station at York, and which has given satisfaction, may be of some interest, as I am not aware that a similar method is in use at any other station.

The plant consists of four over-compounded dynamos direct driven by Willans engines, run in parallel on to the station 'bus bars, from which three circuits are fed, one of which carries both arc and incandescent lamps. The only ammeters used are in the lamp circuits, and are not available for ascertaining the loads of the different machines. The voltmeters are usually kept on the pilot wires to indicate the difference of potential at the ends of the mains, but they are, of course, available for adjusting the difference of potential of any incoming machine to that of the 'bus bars. Shunt regulating resistances are provided, but they all work together, and independent control of the shunt excitation is not possible or necessary. These resistances are only occasionally used to regulate the difference of potential at the ends of the mains.

The usual cable connecting the + brushes of the machines is used, and a switch to this cable is provided for each machine, so that they may be dropped in or out, as the requirements of the load necessitate. Three small ungraduated indicators, consisting of a *polarised* needle with a few turns of wire round it, are also provided, and one of these is connected between the + brushes of each *pair* of machines. If at any time current passes between two machines when running in parallel, part of it passes through the indicator branch, and deflects the needle, and the winding of the coils of the indicators is such that the pointer is deflected towards the number of the machine which is giving current to the other. The switchboard attendant, who is also the engineer, simply lowers the speed of one engine, or increases the speed of the other, as may be necessary, until the pointer becomes vertical. The indicators, of course, are so placed on the switchboard that they can be seen when adjusting the speed regulator of any engine. Nearly the whole of the regulation is effected in this way, the shunt resistances being only occasionally used for adjusting the voltage as indicated on the pilot wires, and never for the adjustment of the load between the machines.

The arrangement, as will be readily seen, is intended to ensure an equality of potential at the brushes of the machines, which, when obtained, ensures against one machine sending current through the other.



Main Cables and Shunt Wires to Switchboard.

Since the fall of potential between the brushes of each machine and the 'bus bars is the same, it is necessary with this arrangement, whether the machines have the same or different outputs, that the resistance of the several machines between the brushes and the 'bus bars (series winding and connecting cables) shall vary inversely as their maximum rated current output. Unless this condition is complied with, the total safe-working capacity of the plant will be lowered.

I enclose a rough diagram to eke out a somewhat imperfect description.

THE DEVELOPMENT OF THE EXPERIMENTAL STUDY OF HEAT-ENGINES.*

BY PROF. W. C. UNWIN, F.R.S.

The request to deliver one of the series of lectures instituted at the desire of Mr. James Forrest carried with it something of the authority of a command. I trust that that will be held to excuse in some measure the undertaking of what I feel is a rather serious and difficult duty. I understand that it was Mr. Forrest's intention that these lectures should illustrate the dependence of the engineer in his practical professional work on the mathematical and physical sciences. They therefore naturally take the form of a review of some branch of engineering with special reference to the scientific principles which have been factors in its advancement.

I selected for this lecture the history of the experimental investigation of the steam engine. On the one hand, the steam engine in its many forms has been the most remarkable of all the machines which are due to the genius of engineers, and the most powerful auxiliary in the expansion during a century of engineering work. On the other hand, the creation of a science of thermodynamics on the basis of the principle of the conservation of energy during the years 1845-1855 is one of the most important advances ever made in scientific knowledge. Between 1855 and 1875 scientific men of very great intellectual eminence prosecuted researches on the action of heat motors as illustrations of thermodynamic principles, and engineers simultaneously invented many improvements and enor-

* The "James Forrest" Lecture, delivered before the Institution of Civil Engineers, May 2nd.

Digitized by Google

mously extended the use of steam power. I shall endeavour to show that the scientific advance and practical improvement of the steam engine were not unconnected.

In a Paper recently read in this Society, an engineer, for whose practical ability and remarkable mechanical ingenuity I have the greatest respect, made the following statement: "A period of 67 years has been required for the development of the principles enumerated by Watt, Trevithick and Grose, and upwards of 40 years have been required for the reduction of the consumption of steam from 19lb. to 13lb. per indicated horse-power hour. . . . In these advances no new principles have been applied and no higher efficiency has been obtained. The progress has resulted from the labours of makers and designers of steam engines, purely scientific investigation having only explained what the steam-engine should do if worked in a manner wholly imaginary." That represents, I believe, a not uncommon opinion, perhaps also a not uncommon jealousy of the intrusion of science in the field of practical engineering. It is curious that the Paper in which this occurs is not a practical Paper at all but a theoretical Paper, in which the author uses the data of Regnault and not altogether correctly applies the methods of Rankine. It may be noted that out of thirty-six engine tests on which the author bases his conclusions, half are engine tests made by professors. It is something that the improvement of the steam engine is attributed to the development of principles laid down by Watt. But when Watt invented the steam engine he was not an engineer; he was a philosophical instrument maker, and he found his principles in the laboratories of Glasgow University. Black's discovery of latent heat gave him the key to the apparently extravagant expenditure of injection water in the model Newcomen engine, and Dr. Cullen's discovery of the low temperature at which water boils in vacuo—he himself states this—led him to perceive that steam would condense in a separate vessel, and to formulate the principle that steam will take the pressure corresponding to the lowest temperature of any part of the space in which it is confined. The writer I have quoted says that "the proposal of Watt to use steam expansively was not the result of abstruse investigations, but was due to the exercise of Watt's common sense." But when Watt patented expansive working in 1782 he had been experimenting incessantly for 15 years on the properties of steam. "If," says this writer, "we confine our attention to the actual steam-engine cycle, it is seen that in reality a properly-constructed steam engine is a very efficient prime mover." But surely some explanation is wanted why we must confine our attention to a cycle which involves the rejection of nine-tenths of the heat supplied into the condenser.

It will be the object of this lecture to show that other scientific ideas of a later date than those of Watt have been operative in promoting the improvement of the steam engine. It is impossible to go back to the mental attitude of 40 years ago, and those who assert that nothing new has been learned in that time forget that in the interval scientific discoveries have become commonplaces, and that they themselves reason and act on them, as M. Jourdain talked prose, without knowing it.

Twenty years ago Lord Armstrong stated that of all the coal raised in this country about one-third was used for household purposes, one-third for generating steam, and one-third for iron-making and manufacturing processes. He remarked that in the first two divisions the waste of fuel was shameful, and that, without carrying economy to extreme limits, all the effects now realised from the use of coal could be obtained by an expenditure of half the quantity. The improvement of the steam engine is mainly due to an incessant attempt to diminish the waste of fuel.

Tests of Steam Engines in Cornwall.

Steam engineers have been face to face with the problem of economy for more than a century. Coal was excessively dear in Cornwall, and as the mines were deepened and more power was required, the cost of working increased ruinously. By reducing fuel-cost Watt saved the mining industry from extinction, and he adopted the plan of taking in payment for his engines a sum reckoned equivalent to one-third of the fuel saved. By agreement with the miners, tests were made and the standard duty of a Newcomen engine was fixed at 7,037,000 foot-pounds per bushel. Regular duty determinations were made for all Watt's engines. Generally they gave a duty of 20,000,000. It is curious that though Watt had patented expansive working, his trials of it were not encouraging, and he did not use expansive working in his Cornish engines. Watt's connection with Cornwall ceased in 1800, the duty determinations were neglected, and the engines deteriorated. Then Capt. Joel Lean, who had reorganised the machinery at one of the mines and effected great economies, started again the system of duty trials. He and his sons carried on the work for many years and published reports of the results of the trials. Of these reports Dr. Pole says, "the publication produced an extraordinary effect in improving the duty of the engines. Engineers were stimulated to emulation amongst themselves. The practice of reporting is thought to have been attended with more benefit to the country than any other single event excepting only the invention of the steam engine itself." I have placed on the wall a short table giving the improvement of duty of the Cornish engines during the period covered by Lean's reports.

Duty of Cornish Engines.

——	Duty in foot-lbs. per bushel (94lbs.) of coal.	Lbs. of coal per I.H.P.-hour (estimated).
Newcomen	7,000,000	26·6
Smeaton	10,000,000	18·6
Watt, 1800	20,000,000	9·3
Lean's Report, 1815	52,300,000	3·6
" " 1827	67,000,000	2·8
" " 1834	98,000,000	1·9
" " 1840	107,000,000	1·7

Highest duty of Mr. Leavitt's pumping engine at Louisville 140,000,000 per 100lb. of Pocahontas coal. Lbs. of coal per I.H.P.-hour, 1·33.

I shall show later that the creation of a new and more scientific system of testing by Hirn and his colleagues in Alsace in 1855 was the starting point of a similar process of improvement. Quite lately there has been a revival of careful and independent engine testing, and of the publication of the results, and records have been established which would have been thought impossible ten years ago.

The history of expansive working in Cornwall is curious. Watt completely understood the principle and patented it. But he failed to make use of it. Woolf and Trevithick reintroduced expansive working, and Woolf tried compound engines in 1812. But the compound engines were not more economical than simple engines. It is clear that the scientific conviction that expansion must be economical held its ground in spite of practical failures, and this led to repeated attempts, till at last an extraordinary amount of success was achieved.

The peculiar character of the load against which the engine worked, the lifting of a heavy mass of pump rods, contributed to force the use of expansive working. To work without shock, a large initial and gradually diminishing effort was necessary. The extraordinary economy obtained was due probably in part to the special action of the steam, the Cornish engine being virtually a compound engine, and the admission surface being protected from cooling to the condenser; partly to the great effectiveness of a steam-jacket in an engine which worked slowly and with pauses at the end of the stroke, partly to the small clearance and separate admission and exhaust valves. The lesson engineers should have learned from Cornish experience was, that in restricted conditions high ratios of expansion were economical. In this case, as in others, later engineers generalised too crudely, and concluded that expansive working was always economical. A new scientific investigation was required to correct the error.

Experiments on Boilers.

To generate steam-power economically the boiler must be efficient and the engine must be efficient, and the conditions of efficiency of engine and boiler are completely independent. Hence the early method of Watt, in which attention was paid only to fuel used and water pumped, has been replaced by a method of independent boiler and engine testing. The boiler uses coal and generates steam; the engine uses steam and generates power. The economy of the boiler is reckoned on the fuel; that of the engine on the steam.

The earliest systematic trials of boilers are recorded in a Paper by Mr. Josiah Parkes in the second quarto volume of the *Transactions* of this Institution. They are interesting as showing how early engineers realised the necessity of studying experimentally the conditions of generating steam economically. Parkes obtained information about the calorific value of different coals; measured the feed and fuel, reduced his results to a rational common standard and recognised the importance of regulating properly the air supply. If his results can be trusted, the general average evaporation in boilers at that time was 7½lb. from and at 212deg. per lb. of coal. With improved firing, and especially with improved arrangements for air supply, the average evaporation was 8¾lb. and the best 10¾lb. A trial in Cornwall is given in which the evaporation was 15½lb. per lb. of coal, but in that case I suppose the measurements or the reduction of the results must have been defective.

As to the calorific value of coal, there has been for a long time no uncertainty of practical importance. The researches of Dulong showed that the calorific value could be ascertained from the chemical analyses very approximately. No doubt there has been a want of a convenient calorimeter for determining directly the calorific value. This want has now been supplied by the invention of the bomb calorimeter, which appears to give very trustworthy results without excessive trouble. Mr. Donkin has made it possible to get a bomb calorimeter in a less expensive form than that first used.

Digitized by Google

Different coals, at any rate the better kinds of coal, do not differ much in absolute calorific value. Used in boiler furnaces they differ more partly from differences of mechanical aggregation, but chiefly because the more bituminous coals require a larger air-supply for tolerably smokeless combustion than those which consist chiefly of fixed carbon. The greater excess of air involves greater chimney waste. It is to test the commercial calorific value that Prof. Schröter has established in Munich a heat laboratory where fuels can be tested on a large scale and under ordinary practical conditions of combustion. The arrangements permit the determination of the exact conditions most suitable for each fuel.

An enormous number of boiler trials have been carried out, but most of them are mere individual tests of very little scientific value. Engineers have been too much under the impression that the evaporation depended chiefly on the type or proportions of the boiler, or the arrangement of the heating surface. But there are no obscure or complicated actions concerned in generating steam. Boilers of all types give nearly the same results provided only proper conditions of combustion are secured. They may differ in cost, in durability, in convenience, but in efficiency they differ less than, I think, is commonly assumed. The following Table shows that boilers of extremely different types, with very different proportions of heating surface and very different rates of combustion, and even with different coals, have all reached evaporations of from 11lb. to 13lb. of water from and at 212deg. per lb. of coal :—

Boiler Trials.

Type.	Ratio of grate to heating surface.	Coal pr. sq. ft. of grate per hour.	Evaporation from and at 212° per lb. of coal.	Coal.
Cornish	—	7·2	11·9	Welsh.
Lancashire	1 : 36	22·9	11·2	Lancashire.
Galloway	1 : 24	8·5	11·6	Anthracite.

„	1 : 61	18·6	12·5	„

Trials of Welsh and North Country Coal.

Between 1857 and 1870 several series of trials were made, partly at the instance of colliery owners, partly under the direction of the Admiralty, to determine the relative value of Welsh and north country coal for generating steam. These trials extended over months and were laborious and costly, and they seem to me to have failed altogether to yield any useful result. In 1857, in trials carried on for many months, the result was obtained that Newcastle coal would evaporate 12·91lb. and Welsh coal 12·35lb. from and at 212deg. per pound of coal. Trials with the same boiler were then carried out under Admiralty direction by Messrs. Miller and Taplin. Their conclusion was that the Welsh coal evaporated rather more than the north country coal. A third series of trials were carried out at Cardiff, and in these the Welsh coal was found to be greatly superior to the north country coal. Finally, in 1881 to 1882, Mr. D. K. Clarke carried out extensive tests, obtaining from both coals evaporation of 12½lb. to 13¼lb. per pound of fuel. Mr. Clarke concludes that when both coals are treated properly they are equal in evaporative power and equally smokeless. How came it about that these long and costly trials gave such uncertain and discrepant results ? Quite similarly discrepant results, I believe, may be found in trials intended to determine the relative efficiency of different types of boilers.

In all these cases the failure to obtain definite and concordant results was due to overlooking the fact that the chief waste, the chief cause of loss of efficiency in the action of a boiler, is the heat carried into the chimney, and that this depends on simple conditions of air supply. In none of these trials was the chimney waste measured, and hence the observers had no key to understanding the discrepant results they obtained. Variations of chimney waste are large enough to swamp all differences due to type of boiler or quality of fuel. The experiments failed to be conclusive from the want of a scientific perception of the importance of determining accurately for each fuel the minimum necessary air supply, and for each trial the proportion of heat lost in the chimney.

Mulhouse Trials of 1859.

The earliest boiler trials carried out in a completely satisfactory way were those made by the Société Industrielle, of Mulhouse, in 1859. The Society offered a prize to the maker of any boiler which would evaporate 1,800lb. per hour at 75lb. per square inch pressure, and which would evaporate 9·1lb. of water from and at 212deg. per pound of Alsatian coal of not very good quality. In those trials the calorific value of the coal was determined, the ashes were weighed and analysed, the amount of air passing through the furnace was determined, the heat loss in the chimney measured, and a fairly satisfactory attempt was made to ascertain the dryness of the steam. With these data a proper balance-sheet of the expenditure of heat could be drawn up. The efficiency of the three competitive boilers, when worked in the way shown to be best for each in preliminary tests, was practically identical and equal to about 70 per cent. With the coal used in these trials 130 cubic ft. of air per pound of coal are chemically necessary for complete combustion. It was found that the reduction of the air supply almost to this limit, and to a point at which there was definitely incomplete combustion, reduced the chimney waste and increased the efficiency of the boiler. In two special trials, each of a week's duration, the evaporation was 9lb., with 331 cubic ft. of air per pound, and 9·53 or 6 per cent. more with 247 cubic ft.

Some striking results, showing the dependence of boiler efficiency on air supply, were obtained by members of the same Alsatian Society, at the works of Dollfus, Mieg et Cie. From several series of trials the following is selected :—

Date.	Coal burned per hour. Lbs.	Cubic feet of air at 0deg. and 0·76m. per lb. of coal.	Lbs. of water evaporated per lb. of coal.
February to March, 1859.	330	206	5·86
	330	204	5·85
	330	165	6·30
	330	139	6·60
	330	120	6·66

Here the efficiency increases as the air supply is diminished, even when it approaches the minimum chemically necessary. There are two ways in which decrease of air supply tends to increase efficiency. The quantity of heated air reaching the chimney is less, and the velocity of the heated gases in the boiler flues is less, so that there is more time for heat absorption.

The determination of the air supply to a boiler is not altogether an easy operation. An anemometer was used in Alsace, and in suitable conditions it will give approximately accurate results. In recent trials chemical analyses of samples of the furnace gases have been made, and the amount of air supplied calculated from the percentage of CO_2. This method is accurate in principle, but the samples analysed are a very minute fraction of the total chimney discharge, and the samples may not be average samples. In some trials in which this method has been used, there are discrepancies in the ratio of the chimney loss and the undetermined loss, chiefly due to radiation, difficult to understand. Neither anemometer nor chemical analyses is suited to serve as a means of regulating the air supply in the ordinary working of a boiler. What is wanted is an instrument as easily read as a pressure gauge and giving continuous indications.

The Dasymeter.

The dasymeter, invented by Messrs. Siegert and Durr, of Munich, is a fine balance in an enclosed case, through which a current of the furnace gases is drawn. At one end of the balance is a glass globe of large displacement, at the other a brass weight. Any change of density of the medium in the chamber disturbs the balance. A finger on the balance moving over a graduated scale gives the amount of the alteration of density. An air injector draws the furnace gas from the flues, and it is filtered before entering the balance case. An ingenious mercurial compensator counterbalances any effect due to change of temperature or barometric pressure.

The dasymeter is usually combined with a draught gauge, and an air thermometer, or pyrometer, in the flue is required if the amount of waste heat is to be calculated. The dasymeter requires initially exceedingly delicate adjustment, and its indications must be checked from time to time by a Bunte's burette. It is set to read zero with pure air, and then any increase of density due to CO_2 is read as a percentage on the scale. When in adjustment it is as easy to read the percentage of CO_2 in the furnace gases as to read the pressure on a pressure gauge. When the dasymeter is fitted to a boiler the stoker has directions to adjust the supply of air so that the furnace gases have about 12 per cent. of CO_2. With practice he learns what alterations of the damper, or fire door, or thickness of fuel on the grate are necessary, or whether an alteration of grate area is desirable. After a little time the percentage of CO_2 can be kept very constant.

The dasymeter is now largely used for boiler furnaces in Germany, and I am assured that in many cases a saving of 20 per cent. of the fuel has been secured. A similar instrument of somewhat different construction, invented by Mr. Arndt, is in use in France and Belgium. The air supply is the one controllable factor in the working of a boiler furnace, and we have trusted far too long to the practical experience of boiler-makers and the common sense of stokers to regulate this important factor in boiler management. We do not trust the common sense of the stoker to regulate the

Digitized by Google

boiler pressure or the water-level, and it is equally necessary, if economy is to be obtained, that he should be supplied with some means of ascertaining definitely whether his management of the fire is good or bad. I believe in good and large installations, at least, it will come to be considered as necessary to have an instrument of the dasymeter type as to have a pressure gauge, and this, I think, may be regarded as a gift of science to the practical engineer.

Experiments on Steam Engines.

It has been seen that Cornish experience pointed to the rule that very large ratios of expansion could be adopted with economy, provided the conditions were those of Cornish engines. Expansion was generally used, but for a time with unfavourable results. Watt's rotative engines gave less than half the duty of Cornish engines.

If anyone would like to see what a curious state of mind engineers were reduced to by the success of expansive working in Cornwall, and its comparative failure elsewhere, I can refer them to a Paper by Mr. Palmer (1838) in the *Transactions* of this Institution. Mr. Palmer found that, while Cornish engineers claimed to have obtained a duty of 70,000,000, or even 100,000,000, per bushel of coal, no Boulton and Watt engine in other parts of the country was doing more than 28,000,000. He proceeds to a mathematical demonstration that, with steam of atmospheric pressure, it is impossible to obtain a duty, with no friction and no loss of any kind, exceeding 44,000,000, and that, with steam of higher pressure used expansively, the duty must necessarily be less. He concludes that the Cornish results are altogether incredible. "Strong indeed," he says, "must be the evidence that ought to induce this Institution to sanction statements of duty more than double that of the best Watt engine, and still more surpassing the limits Nature has assigned to steam to perform." With the help of more accurate science, we have been able to actually obtain a duty about five times as great as that supposed to be the limit of possibility by Mr. Palmer.

Isherwood's Experiments on Marine Engines.

About the year 1860, Mr. Isherwood, chief engineer of the United States Navy, began a series of systematic tests of engines and boilers on a very large scale, and with resources only available in a Government establishment. The trials were made with skill and determination; and the substantial accuracy of the results, startling as they were, has never been questioned. The service Mr. Isherwood rendered to steam engineering deserves the fullest recognition; and if some of his opinions from his earlier Papers are quoted which he would not now defend, it is only to show what was the condition of opinion in the mind of a very advanced engineer 30 years ago.

Mr. Isherwood seems early to have doubted the economy of expansive working, which, he says, had long been an undisputed article in the creed of the engineer. By what he terms "a simple arithmetical calculation suited to the meanest capacity," he endeavours to show that the advantage of expansive working has been over-rated. In this calculation he makes a blunder, often reproduced since, in assuming that the whole work done in the cylinder, during admission as well as expansion, is due to heat obtained by condensation of steam. The error was unfortunate, because then and since it has diverted attention from the true cause of waste in the action of steam. Isherwood did find by his experiments a large cylinder condensation, but he was too acute to attribute the whole of it to work done. He pointed out clearly the action of water on the cylinder wall in abstracting heat during exhaust, which would have to be supplied by condensation during admission. Further, he pointed out that priming water in the steam produces a loss greater than could be accounted for by mere abstraction of the heat in the priming water from the boiler. In his earliest Paper he argues against the utility of jackets and against superheated steam, but experiment soon after led him to modify his conclusions on both these points.

All Isherwood's trials of large marine engines showed that when expansion was extended beyond exceedingly small limits it caused not an economy but a waste. In his second volume he sums up his results as proving that when cut-off is earlier than 0·6 or perhaps even 0·7 of the stroke, the consumption of steam reckoned on the work is increased. Curiously enough, this led him to attack the compound engine. From the quantities in the Table of Experiments, he says: "It will be seen how useless in point of economic gain is the preposterous arrangement of steam engine known as the double cylinder, Woolf, or Hornblower engine. . . . Opposed to these facts, the declarations of interested patentees and engine builders must be classed in value with those set forth by quacks in advertisements of their nostrums." This is from a Paper dated 1865, and it is curious because Isherwood generally saw clearly enough the danger of drawing sweeping conclusions from narrow experimental premises.

Isherwood's experiments were made on large, low-pressure, slow engines, with large clearances, without jackets, and very great cylinder condensation. In these conditions, widely different from those of Cornish engines, any expansion, except to a very small extent, is uneconomical if regard is paid to indicated power, and still more, as Isherwood showed, if regard is paid to effective power.

Trials of Michigan. Isherwood, Michigan, 1861.

Cut-off.	I.H.P.	Steam per I.H.P.-hour.	Steam per effective H.P.-hour.
		Lbs.	Lbs.
0·92	301	40	43
0·70	211	35	38
0·44	204	33	36
0·30	134	35	39
0·25	118	34	39
0·17	74	37	44
0·09	61	46	61

The proper lesson from Isherwood's results was merely that certain conditions must be observed to secure economy in expansive working. Unfortunately, more generally the conclusion was drawn that the Cornish results were not to be trusted, and that expansion was not economical, and Isherwood's own language lent authority to the least accurate view of his results. To obtain greater insight into the true action in the cylinder, and to find a reconciliation of the Cornish and American tests, experiments of a much more refined character were wanted and insight due to wider scientific knowledge.

The Physical Properties of Steam (Regnault).

No useful progress could be made with a theory of the steam engine, no accurate reduction even could be made of the results of engine tests, without exact determinations of the relations of pressure, temperature, volume, latent heat, and liquid heat of steam. It was fortunate, therefore, that about 1840, M. Regnault obtained the means from the French Government to make a series of researches on the physical properties of steam with splendid instrumental appliances. He wisely carried out his determinations over a very wide range of conditions, and spared no labour or trouble in attaining accuracy. Regnault's results were of the greatest importance as a foundation for accurate study of the steam engine.

The Foundation of Thermodynamics (Carnot and Joule).

The next important step was the discovery of the equivalence of heat and work. Joule's investigations began with an attempt to improve Sturgeon's magnetic engine. He was so led to consider motive-power problems from the engineer's standpoint, as a question of duty, or of something obtained for something expended. He ascertained the amount of electric current produced by the chemical combustion of a given amount of zinc, and comparing his results with those obtained in good steam engines, he concluded that, making the largest allowance for possible imperfections of his magnetic engine, it was never likely to be a rival in economy to the steam engine. That was a negative but a useful result. It closed one direction of useless endeavour only too likely to attract the inventor.

One of the effects of electric action which Joule noticed, was the heating of his conductors, and it was to the measurement of this heating effect he next addressed himself. The heat developed in the conductor by the electric action due to elements combining in the galvanic cell, was found to be identical with that which would be generated by the direct combustion of the same elements. Finally he came to consider the relation between the mechanical work expended in driving a magneto-electric machine and the heat developed in the external circuit of the machine. He concluded that for 838 foot-lb. expended, a pound-degree of heat was generated. Later experiments corrected this value, but the discovery of the equivalence of heat and work was made.

Here, for a short time, Joule was misled by his own discovery. Examining the case of the steam engine, he found that of the heat generated in the boiler furnace less than one-tenth was actually converted into work. On that he too hastily assumed that this was a measure of the remediable imperfection of the steam-engine. It was not till six years after that he understood the physical limitations to the conversion of heat into work. The motivity of heat, or its capability of conversion into work, depends on local conditions. To increase the proportion converted in the steam engine, except so far as decreasing subordinate losses is concerned, it would be necessary to remove it to another planet where more favourable conditions for heat-conversion exist.

As early as 1824, 20 years before Joule's discovery, Sadi Carnot, in a remarkable pamphlet on the Motive Power of Heat, demonstrated the fundamental principle that the amount of work obtainable from any given quantity of heat cannot exceed a quantity, proportional to the fall of temperature. Unfortunately, adopting, though with hesitation, the view held in his time that heat is material and indestructible as heat, he coupled with his

Digitized by Google

true principle the false corollary that all the heat entering an engine is discharged in the condenser. Joule in 1845 found this principle of Carnot, and looking to the corollary as essential, supposed the principle itself to be false. He failed to perceive that Carnot's principle was the essential supplement to his own discovery, and that it showed why the apparent efficiency of the steam engine is so low. It took six years before Joule's and Carnot's principles were reconciled, and for three of them even Lord Kelvin refused to accept Joule's discovery because it apparently conflicted with the principle of Carnot.

Permit me a very short digression. In popular writings nothing is commoner than to find the efficiency of electric machinery and of steam machinery contrasted to the great discredit of the latter. The dynamo, it is said, has an efficiency of 90 per cent. to 95 per cent., the steam engine an efficiency of only 10 per cent. What a barbarous machine, after all the labour of a century, the steam engine must be! The comparison is generally made by an electrical engineer, and the first reflection which occurs to one is that of all people the electrical engineer should be the last to abuse the steam engine; for, whatever may be the case in some future century, at present the dynamo is absolutely dependent on the steam engine. Without the steam engine the dynamo would be a useless mass of metal and wire. But passing over the moral aspect of the question, the ingratitude of the electrical engineer, the comparison is an unfair one, and shows a want of apprehension of that important law of the motivity of heat which is one of the two fundamental laws of thermodynamics. Heat energy is undirected or mob-energy. It lies in the nature of the terrestrial conditions in which use has to be made of it, that only a fraction is convertible into directed or mechanical energy. The task of the steam engine is to do its best with the fraction which is convertible, and in that point of view it is not an inefficient machine. The dynamo has a much easier task. Energy is supplied to it in its directed or wholly convertible form, and naturally in transforming one kind of directed energy into another kind of directed energy only a small fraction need be wasted.

The Founders of the Rational Theory.—Rankine, Clausius, Zeuner.

The impetus given to the study of Thermodynamics by the discovery of Joule and the perception of the fundamental importance of Carnot's theorem was enormous. Heat problems could now be brought out of the region of mere empirical solutions, and treated from the rational standpoint of an exact science, and the steam engine as the most important example of heat transformation attracted at once the attention of scientific men of commanding intellectual ability. In a very few years Rankine and Clausius had built up a strictly rational mathematical theory of the steam engine, and a little later Zeuner carried further the analysis of some of the more subordinate details. The theory, with one exception, to be referred to presently, took account of all the actual conditions under which steam is used, and furnished exact rules for the relation of steam expended and work done for all arrangements of the actual steam engine practically adopted. Subject to only one restriction of importance, the rational theory would have given the means of determining by nearly exact calculation the relative economy of different types of engines, the precise advantage in any given case of any particular ratio of expansion, the loss due to clearance and other questions of that kind. No physical theory of any machine was ever constructed more complete or on less exceptional data.

It was just at this time that the experiments of Isherwood were published, and a comparison of experimental results and theoretical calculations showed directly a very large discrepancy. The steam consumption in some trials was 30 per cent., 40 per cent., or 50 per cent. more than it should have been in the assigned conditions of working according to the rational theory. Some action of quite governing importance had obviously been neglected in the theoretical analysis.

A rough illustration will perhaps make clear where the defect of the rational theory lay. Suppose a good water-wheel driven by a fall of water. The mechanical action of the water is of a simple kind, and a theory is easily constructed which would give the relation of the water expended and the useful work done. Now suppose that, unknown to the constructor of the theory, there existed a large leakage from the head race to a reservoir on the supporting walls. Obviously the water expended would be greater than the calculated expenditure. The error of the calculation would not be due to any defect of the theory of the water-wheel, but to an extraneous and additional action which had not been taken into account. There was a neglect of a very similar kind in the rational theory of the steam engine, a leakage of heat treated as negligible in the theory which is, in fact, far too large to be treated as negligible in the practical working of the engine. Rankine and Clausius and Zeuner were well aware that the operation of the steam in the engine has to be carried out in a metallic cylinder capable of absorbing and giving up heat. But the conditions in which this exchange of heat occurs are complicated and very difficult to include in a mathematical analysis. They left the heat exchange with the cylinder wall out of the analysis as a matter which could be allowed for by some empirical coefficient. No doubt they altogether under-rated the enormous facility of heat exchange which arises out of the contact between a conducting cylinder wall and a vapour in a condition of the greatest instability and liable to condense or evaporate on the slightest change of thermal condition.

(To be concluded.)

THE MADAGASCAR CABLE.*

The French Government received on April 1st telegraphic advice of the completion of the laying of the Majunga cable under the conditions and within the period stipulated. In a previous issue we published the terms of the contract, dated December 23rd last, for the establishment of this cable, the length of which is 405 nautical miles. We recall to the recollection of our readers that half the cable was to be constructed at the Calais works of the Société Industrielle des Téléphones, and half in those of M. Gramont, at St. Tropez; that the steamer "François Arago," belonging to the Société des Téléphones, having on board the 425 kilometres (228 knots) of cable manufactured by that Company, left Calais on February 8th for St. Tropez to embark the 330 kilometres (285 knots) manufactured by the firm of Gramont; that the ship sailed thence on February 27th; that immediately on its arrival at Mozambique on March 19th she commenced the laying, satisfactorily completed on April 1st; and that the cable was at once opened to official correspondence.

This is an undeniable success for the contractors, especially if account be taken of the restrictions imposed by the Government. We are happy to be able to congratulate them. But it is a far cry to magnify it into a *tour de force*, as it is termed in a stereotype article, which has been reproduced in numbers of journals, inspired by the contractors to glorify their feat. In fact, we are in a position to know that an English company had offered to make and lay a new cable within a maximum period of 65 days from date of contract in consideration of a sum of 1,350,000fr. (£54,000). For the same operation the contractors were allowed a period of 98 days and a sum of 2,100,000fr. (£84,000). Under such circumstances, is it reasonable to believe, without in any way depreciating the merit of the enterprise, that a *tour de force*, unprecedented in the annals of submarine telegraphy, has been achieved? In addition, we ask in what has this excess of price, amounting to 750,000fr. (£30,000), transferred under the pretext of patriotism from the pockets of the taxpayers to those of the contractors, benefited the general interest? And we can hardly comprehend why an industry which, by every means of publicity and otherwise, makes incessant appeals in order to obtain the financial assistance of the State, should profit by circumstances in which the Government has need of its services to form a coalition, and tie it down by a Draconian contract bearing a profit of cent. per cent. We doubt whether the most ardent Chauvinism and patriotism have reason to be satisfied with such a result, which, beyond all argument, makes it comprehensible why France has not a submarine system, and why she cannot have one while the same practices are followed—at least while the State continues to pay for cables at double their real value. It is very evident that it is not the public who, under similar conditions, will be tempted to place its capital in French submarine telegraph enterprises.

The above note was already in the press when our attention was called to an article in a morning paper which pretends to justify the difference between the price asked by the English and that granted to the French contractors by the following:—"Want of space prevented us yesterday citing in full the particulars furnished by one of our *confrères* concerning the conditions under which the English proposed to establish the Madagascar cable. In fact, our quotation stopped at the passage mentioning the price of 1,300,000fr. asked by the English against that of 2,100,000fr. granted to the French contractors. It is right to complete these particulars by the following, which amply explains this difference, which may have surprised our readers. The English propositions emanated from the group of companies by whose cables all the traffic from Madagascar passes, starting from Mozambique, where the messages enter the English lines, to Marseilles. The tariff on these messages is 10fr. per word, and the probable traffic for the first year is estimated, in consequence of the expedition, which will necessitate constant communication with the capital, at about 300,000 words, representing receipts of 3,000,000fr.—a considerable profit without expense to the recipients. This is the reason which permits the English contractors, assured in advance of so profitable a compensation, to lower at will their charge for establishing the cable in order to foil the efforts of our national industry. What they lose upon construction they will gain in the receipts which the establishment of the Majunga-Mozambique line will bring to their

* From *Bulletin de l'Électricité et de la Télégraphie* of April 7th.

Digitized by Google

cables. One can comprehend, under these conditions, that competition was easy."

This explanation may be ingenious, but it is absolutely devoid of foundation. In the first place, the proposition for the establishment of the cable for the sum of 1,350,000fr. emanated from a construction company which has absolutely no interest in the cables by which the traffic from Madagascar, between Mozambique and Marseilles, will be carried. The proposal had only in view the profit upon the sufficiently remunerative price of 1,840fr. per kilometre (£136 per knot), which it is ridiculous to seek to qualify as manufacturing at a loss. In the second place, in the negotiations relative to the establishment of the Madagascar cable, which have in fact taken place with the group of companies who themselves work the telegraphic lines between Mozambique and Marseilles, it is well known that these companies offered the Government a reduction, on the tariff of 10fr., of half for official messages and of about 25 per cent. for private telegrams. Calculating, on the estimate of our contemporary, upon a traffic of 300,000 words, this arrangement would have effected an annual saving of more than 1,000,000fr. (£40,000) to France, apart from the difference in the price of the cable.

PHYSICAL SOCIETY.

At the Ordinary Meeting of this Society on April 26th, Mr. Walter Baily, Vice-President, in the chair.

Prof. S. P. Thompson read a Note on

"A Neglected Experiment of Ampere."

Ampère, in 1822, made an experiment which, if it had been properly followed up, must have led to the discovery of the induction of electric currents nearly ten years before the publication of Faraday's results. While attempting to discover the presence of an electric current in a conductor placed in the neighbourhood of another conductor in which an electric current was flowing, Ampère made the following experiment:— A coil of insulated copper strip was fixed with its plane vertical, and a copper ring was suspended by a fine metal wire so as to be concentric with the coil, and to lie in the same plane. A bar magnet was so placed that if an electric current was induced in the suspended ring a deflection would be produced. No such deflection, however, was observed.

In 1822, in conjunction with De la Rive, Ampère repeated this experiment, using in place of the bar magnet a powerful horse-shoe magnet. He describes the result in the following words:—"The closed circuit, under the influence of the current in the coil, but without any connection with this latter, was attracted and repelled alternately by the magnet, and this experiment would, consequently, leave no doubt as to the production of currents of electricity by induction if one had not suspected the presence of a small quantity of iron in the copper of which the ring was formed." This closing remark shows that they were looking for a permanent deflection. When, however, Faraday's results were published in 1831, Ampère, after again describing the experiment made in 1822 by himself and De la Rive, says: "As soon as we connected a battery to the terminals of the conductor the ring was attracted or repelled by the magnet according to the pole that was within the ring, which showed the existence of an electric current produced by the influence of the current in the conducting wire."

Verdet, when describing the above experiment, falls into a curious error. He says the apparatus consisted of a ring of fine copper wire, suspended by a silk thread in front of the pole of an electromagnet in such a way that the plane of the ring was parallel to the plane of the turns of wire on the electromagnet. On making the current the ring is said to have been repelled, but this deviation did not persist, and on "breaking" the current the ring was attracted, also only momentarily.

Mr. BLAKESLEY did not feel quite confident that in Verdet's form of the experiment there would ever be attraction. He also pointed out that with an alternating current the disc would tend to set itself parallel to the lines of force of the electro-magnet. With reference to repulsion by alternating currents in one of Elihu Thomson's experiments, where a sphere is supported over an alternating pole, a screen being placed so as to partly shield this sphere, there is generally a misstatement as to the direction in which the sphere rotates. It rotates in such a direction that the part of its surface next the magnet moves towards the edge of the screen.

Dr. BURTON said that from the fact that when the current on the electro-magnet in Verdet's experiment is broken, the induced current in the ring is in the same direction as the current in the magnet, and the ring will be attracted.

Mr. BOYS confirmed Dr. Burton's statement. He recommended setting the ring at an angle of 45deg to the lines of force, under which circumstances a rotation would be obtained. A distinction must, he pointed out, be drawn between such an experiment as that of Verdet and those of Elihu Thompson. The repulsions observed in these latter were only due to the "lag" in the induced currents caused by self-induction. The best materials to use for all such experiments were magnesium and aluminium, since for a given mass these had the highest conductivity.

Mr. W. G. Rhodes read a Paper entitled

"A Theory of the Synchronous Motor."

The object of this Paper is to give as simple a treatment as possible of the mathematical part of the subject, and to give theoretical proofs of some experimental facts. Starting from the energy equation

$$p + c^2 R = C E \cos \psi,$$

where p is the output of the motor, R the resistance of the armature, c the current through the armature, E the E.M.F. applied to the motor terminals, and ψ the phase difference between c and E, the cases of maximum output, zero output, minimum current at zero power, and maximum phase difference between c and E are considered. These results are, for the most part, obtained directly from the energy equation. The latter part of the Paper is devoted to a discussion of the phase relationships between the current and the E.M.F.'s in a plant consisting of a generator and motor, and to the variations in the armature reactions in both generator and motor. A theoretical proof is given of the fact, observed by Prof. Silvanus Thompson and others, that an over-excited synchronous motor acts as a condenser, and tends to make the current lead before the generator's E.M.F.

Prof. S. P. THOMPSON said that the mathematical part of the Paper was much simpler than that in previous investigations on this subject, and the method of arriving at the results by rejecting imaginary roots of the equations was particularly neat and instructive. The part of the Paper relating to armature reactions and phase relationships was quite new. Two results deserved special attention; first, that the maximum current at zero power was the same as if the circuit was non-inductive; second, that the maximum current at zero power was double the current corresponding to maximum output.

Mr. BLAKESLEY said that the Paper did not consider the stability of the system, and he thought some of the results corresponded to regions of instability.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, May 10th.

Iron and Steel Institute.

10:30 a.m. Annual Meeting at the Society of Arts, John-street, Adelphi.

Physical Society.

5 p.m. Meeting at Burlington House. The following Papers will be read: (1) "On the Iodine Voltameter," by E. F. Herroun; (2) "A New Method in Harmonic Analysis," by A. Sharp.

MONDAY, May 13th.

Society of Arts.

8 p.m. Cantor Lecture, "Recent American Methods and Appliances Employed in the Metallurgy of Copper, Lead, Gold and Silver," by James Douglas.

Northern Society of Electrical Engineers.

8:30 p.m. Ordinary General Meeting at the Palatine Hotel, Hunt's Bank, Manchester. The following Paper will be read: "The Uses of Accumulators," by J. C. Howel

TUESDAY, May 14th.

Institution of Civil Engineers.

8 p.m. Ordinary Meeting in the temporary offices, 9, Great George-street.

WEDNESDAY, May 15th.

Royal Meteorological Society

7:30 p.m. Ordinary Meeting at the Surveyors' Institution, 12, Great George-street, S.W.

Society of Arts.

8 p.m. Ordinary Meeting. The following Paper will be read: "Means for Mitigating the Fading of Pigments," by Capt. W. de W. Abney, F.R.S.

Royal Microscopical Society.

8 p.m. Meeting at 20, Hanover-square, W.

THURSDAY, May 16th.

Royal Institution.

3 p.m. Afternoon Lecture. "The Liquefaction of Gases," by Prof. Dewar.

FRIDAY, May 17th.

Institution of Electrical Engineers.

8 p.m. Students' Meeting in the Library of the Institution, 28, Victoria-street, S.W. Paper to be read: "Aluminium," by Gerald C. Allingham.

The Bakerian Lecture.—This lecture was delivered before the Royal Society yesterday by Mr. A. Vernon Harcourt, F.R.S., and Mr. W. Esson, F.R.S., its title being "On the Laws of Connection between the Conditions of a Chemical Change and its Amount."

SPECIAL NOTICE.

Last week's number of "THE ELECTRICIAN" commenced Vol. XXXV. and contained (Gratis) the Index to Vol. XXXIV. Complaints of non-receipt should be promptly made to the Publisher.

Owing to the growth of the electrical and allied industries the demands for space in "THE ELECTRICIAN" are, for the greater part of the year, so pressing that a permanent increase in the size of the journal has become necessary. To meet the increased cost involved by this step, and by other improvements, such as heavier paper and more numerous illustrations, the price of "THE ELECTRICIAN" has from May 3rd been advanced to 6d. Hitherto this sum has been charged when the number has contained a Supplement, and, as the industries grow, these may be more frequently necessary; but the practice of charging extra for Supplement numbers as issued will be discontinued.

The Subscription to "THE ELECTRICIAN," commencing with Vol. XXXV. (May 3, 1895), is as follows:—

	YEAR.	HALF-YEAR.	QUARTER.
United Kingdom......	26s. 0d.	...... 13s. 6d.	...... 7s. 0d.
Postal Union	30s. 0d.	...... 16s. 0d.	...... 8s. 0d.

(Post free, payable in advance.)

NOW READY.—Vol. XXXIV. of "THE ELECTRICIAN," bound in strong cloth. Price 12s. 6d., post free 13s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

THE EXPERIMENTAL STUDY OF THE STEAM ENGINE.

Prof. UNWIN seems to have some hope of converting the rule-of-thumb engineer to a belief in scientific methods, and his lecture of last Thursday night was, to a large extent, devoted to this object. He pointed out that WATT experimented for fifteen years; HIRN tested JOULE's principle on an actual steam engine; and all engineers who improved the steam engine by more recent experiments, whether they were college professors or manufacturers, like the late Mr. WILLANS, have thought in the language of RANKINE. Even if the infidel were to be converted by this exhibition of historical fact, he would say that all Prof. UNWIN's objects would be satisfied by the existence of one or two scientific engineers in each generation; but, indeed, the conversion of the man who poses proudly as a non-scientific engineer is out of the question, for there can be no belief in scientific methods where there is no scientific knowledge. Happily, Time is quickly making all attempts at conversion unnecessary. Rule-of-Thumb is in the position of Private MULVANY—"I was a corp'ral wance, but now I am rejuced." Whether or not any of the older engineers read Prof. UNWIN's address, it will be eagerly welcomed by the

Digitized by Google

younger generation, among whom the competition is strong enough to assure us that in the future there will be, with practical engineers, a happy and correct admixture of theory and rule-of-thumb.

The lecturer gave, very shortly, an account of the more important measurements made upon steam engines during the century. Engineers have discussed these measurements with such a mathematical and physical knowledge of the properties of water-stuff, with such knowledge of the principles of thermodynamics, and above all with so much of that kind of knowledge which we call common sense, that they have been able to develop the steam engine to its present satisfactory state. Undoubtedly the progress was very slow till about twenty-five years ago. Prof. Unwin is, we think, unnecessarily severe upon the electrical engineer. It is true that he has occasionally called attention to the fact that good steam plant, even under steady loads, gives out usefully only one-tenth of the energy of the coal. But there is no ingratitude in this; it is a fact that ought to be borne in mind continually, and when the electrical engineer goes on to point out that it is in the electrical direction that we must look for many times this efficiency in obtaining mechanical energy from coal, he does this modestly, for he knows well his dependence upon the steam engine at present. It is really not fair to charge us with either ingratitude or impertinence, and we might answer like the Indian chief, to whom the Nabob said, "Are you yet to learn who that Colonel Clive is, and in what station God has placed him?" "*I* affront the Colonel? I, who never get up in the morning without making three low bows to his jackass!" If there is any ingratitude, surely it is in the steam engine manufacturers, for the improvements in stationary engines made during the last 15 years have been very greatly due to the fact that electrical engineers can measure their energy and power with wonderful accuracy, and they demanded some approximation to accuracy in steam engine measurements; hence, instead of only one or two mechanical engineers being interested in accurate measurements of power and steam, almost every manufacturer is now so interested.

We question whether any middle-aged or young manager of works does not know now, exactly, what are the directions in which steam engine improvement is to be looked for. Watt was right; there must be great expansion; this leads to the use of high-speed and high initial pressure, and some plan to prevent cylinder condensation. Expansion in successive cylinders, steam jackets, the use of superheated steam—these are the plans recommended; the first two alone are in use to any great extent at present. It has been abundantly proved that jacketing leads to considerable economy if applied to a single-cylinder engine which previously gave bad results, but if applied to a three-cylinder engine in which there was previously not much cylinder condensation, although there is always an increased economy, it is now not very marked. The jacket steam must be very much warmer than the working steam if it is to prevent all condensation. When steam and water are alone present in the same vessel, and there is a difference of temperature between them, there is a condensation or vaporisation—what may be called an interchange of heat—which is exceedingly great compared with anything that ever occurs by radiation or conduction or convection between any body and a true gas, such as superheated steam. It is, then, to superheating that the modern engineer is now directing his best attention. It may be impertinent for the electrical engineers to venture a suggestion, but we should like to say that there is a method of preventing condensation when ordinary dry steam is used, which seems quite unknown to practical engineers, but which deserves experimental attention, namely, mixing with the steam either air or some other gas, or a vapour which has a lower boiling point than steam. Tests might easily be carried out with non-condensing engines at first. Prof. Osborne Reynolds showed, about twenty years ago, that the presence of a small quantity of a gas very greatly retards the condensation of steam when suddenly admitted to a cold vessel. At present we can only say that it is by superheating that the most economical steam engine result has yet been obtained for any engine of any type or size. Prof. Schröter, using superheated steam in a compound condensing engine of 60 I.H.P., with only the low-pressure cylinder jacketed, had a steam consumption of only 10·2lb., and a coal consumption of 1¼lb. per hour per indicated horse power.

We are glad to see that Prof. Unwin dwells upon the fact that the Willans rule—the total water per hour is, within reasonable limits, a linear function of the power, if speed and ratio of expansion are kept constant—is in agreement with Rankine's rules if we assume with Cotterill a constant fractional condensation. In some engineering classes known to us, the students have illustrated this by numerical examples, and also generally, ever since Mr. Willans published his results. The lecturer has not given us enough. He has condensed a great deal of information and suggestion into small compass, but it is quite evident that he himself regrets that so much condensation is necessary. In Prof. Cotterill's book we have a valuable treatise on this subject, but for the practical engineer, even if scientific, there is almost too much speculative mathematical detail. In Prof. Ewing's delightfully clear treatment we regret the absence of detail. Prof. Unwin has all the information of what has been done and is a-doing in the experimental study of the steam engine, and, in addition he combines scientific accuracy with a knowledge of the methods of the manufacturer and the user of engines, and whilst we are thankful to him for his occasional short contributions to discussions of Papers, and for this valuable lecture, we think that the engineering world would like to see him publish a much more extensive treatment of this subject, as he in a manner did in the case of his Howard lectures on "The Development and Transmission of Power from Central Stations." Steam plant economy under steady load is not so important for the central station engineer as its economy under loads which vary greatly during the 24 hours. But, as Mr. Kipling says, "That's another story." We can only say again that we are grateful to Prof. Unwin for what he has already given, and we ask for more.

NOTES ON SUBMARINE CABLE WORK.

BY H. D. WILKINSON.

(Continued from page 13.)

34. Cable Currents.—In a submarine cable there are various currents prevalent, arising from different causes, which interfere generally with testing. To eliminate their effect is the general aim in the best methods. It is a first essential to have the various currents clearly defined in the mind, and form a separate idea of the action of each, although they chiefly act together. These currents are considered separately as follows:—

(1.) *Earth Currents.*—These currents are due to natural causes, and arise chiefly from climatic conditions and magnetic disturbances. The varied rate of evaporation and condensation in different localities produces different states of atmospheric potential which act inductively on the earth. In two distant

Digitized by Google

localities the earth may be at very different potentials, and a current then flows from the higher to the lower potential.

The direction of such currents may follow or cross the line of a cable, and if the conductor is in connection with earth at both ends, a part of the earth current will flow through it. Not only so, but, when the cable is insulated at both ends, induced currents will pass in the cable following every variation in strength or direction of the earth current.

Before condensers were used at the ends of a line, as they are now, the cable was in connection with earth through the signalling instruments, and earth currents flowed directly into it. The effect of this was that the zero on the mirror or recorder followed the waves of earth current. A long scale had to be provided to accommodate the mirror spot, which at times went off altogether and had to be brought back by the controlling magnet.

The direct flow of earth current is now prevented so far as signalling is concerned by condensers placed between the instruments and line; but in testing, of course, the line must come direct on to the bridge and galvanometer, which offers a path for earth currents by the galvanometer and bridge to earth. The extremes of these two natural causes—namely, lightning and magnetic storms (such as accompany the appearance or disappearance of sun spots)—are alike dangerous to the insulation of the cable and the signalling instruments, and, therefore, while a storm lasts the cable is put to earth for safety. Earth currents are quite independent of any testing current, and, as we have seen, flow in cables whether earthed or free, and whether perfect or faulty. They are sometimes so unsteady that it is impossible to make a test, but if fairly steady their

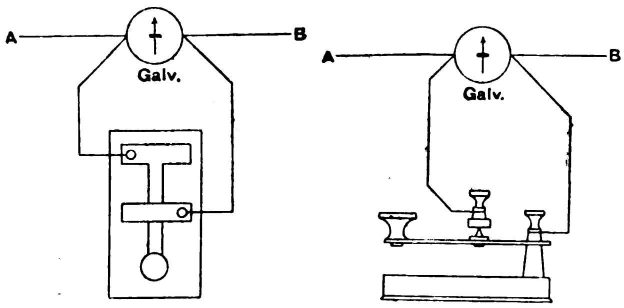

FIG. 105.

effect can be satisfactorily eliminated by (1) using reversals of current, (2) reading to "false zero," or (3) using two different strengths of current and reading to instrument zero, as in the Mance test.

(2) *Electrostatic Charge and Discharge Currents.*—These momentary and violent rushes of current take place on the application or disconnection of the testing battery. Immediately the battery contact is made, a strong, but momentary and gradually decreasing, current rushes into the cable. The greater the E.M.F. of the battery and capacity of cable the stronger will the charge be.

On releasing the contact key (so putting cable to earth) the accumulated charge is dissipated and produces a similar rush of current out of the cable, at first very strong and gradually dying away. These currents are not permitted to pass through the galvanometer, which is ordinarily short circuited by a small key (as in Fig. 105).

When the key is at rest, as shown, the galvanometer is protected, and currents passing between A and B are short-circuited through the key. After a few seconds, when the rush of charge or discharge has subsided, the key is opened (at first by tapping until the bridge is balanced) and then held down by a catch provided for the purpose in order to watch the behaviour of a fault by the spot of light.

(3.) *Natural Current from a Fault or Break.*—There is generally some current originating from the voltaic couple formed at the fault. Currents due to this cause are generally feeble, and may be treated as earth currents and eliminated with them by the above-mentioned methods.

(4.) *Polarisation Current from a Fault or Break.*—Under the action of current from a testing battery the fault or break becomes polarised or charged like a secondary cell, and an opposing E.M.F. is set up in it called the E.M.F. of polarisation. On releasing the battery key (which disconnects battery and puts cable to earth), the charge stored at the fault is discharged through the cable, producing what is known as the polarisation current. Its chief characteristic is that, from the moment it commences to flow, it falls quickly and steadily in strength, owing to the fall in the E.M.F. of polarisation. The potential active in charging the fault is not the full potential of the battery, but something less, depending on the distance of the fault.

The effect of the polarisation current can be eliminated by the same methods as for earth current. The two currents, in fact, combine and form one for the time. If reversals are used, the zinc current can generally be kept on; but the copper current can only be put on for a second or two, as it may run the resistance of the fault up to something very high. If the zinc current only is used, and the balance taken to false zero, the latter must be observed as soon as possible after the battery is disconnected, in order that it may represent the strength of polarisation current active during the test. The polarisation current may also be neutralised for a sufficient time to get a good test by putting a current on the cable for a few seconds in an opposite direction before balancing the bridge.

35. **Balancing to False Zero.**—As almost all fault testing is to false zero, it may be well to make this clear at the outset. What is termed "false zero" is the position of the spot of light when the testing battery is disconnected, and the galvanometer short-circuit key open. The deflection is due to any current or combined currents that may be passing in the cable. By balancing the bridge to this deflection as zero, the effect of the current or currents in the cable is eliminated. The results obtained are also true for either direction of testing current; and, therefore, the false zero is well suited for tests of faulty cables, as readings can be taken by the zinc current only, which opens and cleans the fault. In observing the false zero it should be borne in mind that the position of the spot should as nearly as possible represent the strength of cable current *at the time of the test.* The false zero deflection of course changes with each adjustment of the bridge, and therefore must be observed again after each alteration of resistance. The difference between the false zero deflection, and the position of the spot at balance gradually becomes less and less as the resistance is adjusted nearer, until finally they both coincide, at which point the bridge is balanced. When the cable current is simply an earth current (as in a good cable) it does not matter whether the false zero is observed before or after each fresh adjustment, because an earth current is not affected by testing current; but when one component of the cable current is due to polarisation of a fault the false zero should be observed as soon *after* each adjustment as possible, as the polarisation current rapidly falls after the battery is disconnected.

With the testing current on, and the resistance in the third arm of the bridge adjusted to bring the spot of light to the false zero mark, the bridge is balanced, and the resistance of the cable so determined is the correct resistance, the interference of polarisation or earth currents being eliminated. The discharge from a cable at the moment of breaking the circuit of the testing battery makes it extremely difficult to know when to read the false zero.

The deflection is a decreasing one, due to both discharge and polarisation; but the discharge at its commencement is at much higher potential than the polarisation current. On the other hand, it falls more rapidly, there being one instant of time when the potential of the discharge at the galvanometer terminal coincides with that of the polarisation. That point is reached in from one to three seconds, according to the length of the cable up to the fault, and it requires a great deal of practice and judgment to catch it at that point. False zero is also spoken of as "cable zero," or "natural zero," as distinguished from "instrument," "scale," or true zero.

In false zero testing a dead-beat galvanometer is the most convenient instrument to use. The movements of the mirror are damped by suspension in a closed tube containing water or air.

Digitized by Google

In Lord Kelvin's dead-beat instrument the mirror is suspended in a tube closed with glass at front and back, in which the space is so confined that when the mirror is deflected it compresses the air within the tube, by which means its oscillations are checked. In the dead-beat instrument shown in Fig. 106 the mirror works in water, and is suspended as shown. The upper end of the silk is taken over a fixed disc D to the pin A, and the lower end to the spring S. (See Fig. 5 reproduced.)

After suspension the silk is drawn taut by shifting the bar P, and, when this is fixed in position by the screw, any further adjustment of the tension can be made by the pin A. This pin passes clear through the block, and its position is adjusted by the nut, so that the silk is not twisted. When adjusted, the whole is put into the tube B, which is filled with water and then closed at the end. This makes an excellent dead-beat suspension. The spot goes very slightly beyond its deflection, then comes back and settles down immediately.

It is very convenient and reliable to balance to false zero when taking an ordinary copper resistance test of a good cable

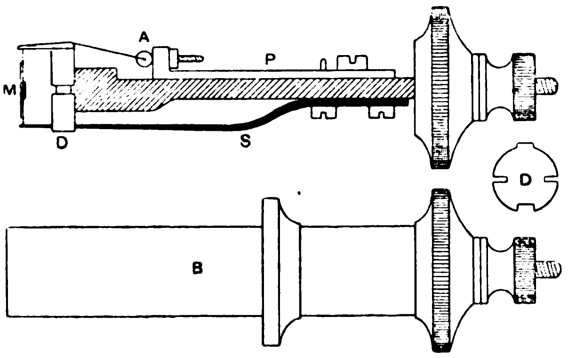

FIG. 5.—(*Reproduced.*)

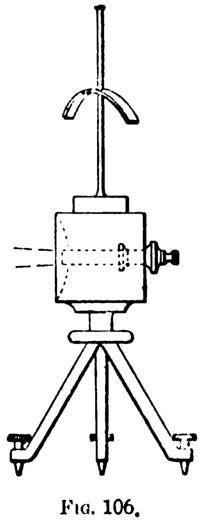

FIG. 106.

with an earth current present. A testing battery current acting in a given direction is either strengthened or opposed by an earth current, and if readings are taken to scale zero the apparent resistance with one direction of current to line is less than that of the other. The arithmetical mean of the two, viz., half their sum, generally gives the result with sufficient accuracy, but should the earth current be strong and the readings with zinc and copper widely differ, the geometrical mean of the two, viz., the square root of the product of the pair, gives a nearer approximation to the true resistance. The observations, however, with both currents are equalised, and a reliable result obtained directly by balancing to false zero.

When, however, (as in a good cable) there is no polarisation to vary the strength of the earth current one is apt at first to overlook the fact that this current (so far as it affects the galvanometer) depends on the resistance unplugged in the bridge. Mr. E. Raymond-Barker, in some communications to the *Electrical Review* of October 10 and 17, and December 12, 1885, has demonstrated by a geometrical treatment of potentials that the resistance in the third arm of the bridge should be as near an approximation as possible to that required to balance, in order to get the right false zero to work to. This is generally known sufficiently near on a good cable, but if not, a rough balance to scale zero should be taken. After that it is a step-by-step process, adjusting the bridge, and observing the false zero between each fresh adjustment, until the bridge is balanced with either direction of current to the same deflection as that observed on the galvanometer when bridge is to earth.

(*To be continued.*)

SERIES ELECTRIC LIGHTING.

The parishes of Kingswood and Keynsham, lying on the Great-Western main line between Bath and Bristol, are likely to attain to some celebrity as being among the first in Great Britain to use series incandescent electric lighting, and since the proprietors of the plant, the "Western Counties Electric Light and Power Syndicate" (Parfitt's Patents), are inviting public subscriptions to form a company on the strength of their experience at these two places, the good inhabitants of Kingswood and Keynsham may wake up one fine morning to find themselves famous.

On Monday last, by the invitation of the proprietors of the Parfitt Patents, a party of gentlemen representing the general, financial, and technical press, and other miscellaneous interests, made the round of the districts, and inspected the two station plants. After the inspection the visitors met in the Grand Hotel, Bristol, and an informal meeting was held under the presidency of Mr. Harry S. Foster, M.P., at which a discussion, also of an informal character, took place as to the advantages claimed for the system by the proprietors. After the introductory remarks of the Chairman, Prof. Silvanus P. Thompson, who, in the capacity of consulting engineer, reported upon the scheme some two years ago, gave a general idea of its chief features, and then various financial and technical questions were asked from the body of the meeting. A lively debate followed, in which the information elicited, although satisfactory to most of the laymen present, was not so convincing to the technical section. The fact is, the proprietors claim too much. Not content with the legitimate field which the system appears to possess, they wish to compete seriously with the usual well tried methods of distributing light and power from central stations.

It is well known that incandescent lighting by series lamps has not been successful, at any rate in any place in Great Britain, although we believe it has attained a certain degree of success at a few places on the Continent, and perhaps in some small installations in America. The difficulty has been two-fold; first, the candle-power provided has generally been too small, and secondly, the failure of a lamp filament has been apt to open the circuit, in spite of automatic devices, and to put out all the lamps on the series. In the experiment made at Barnet a few years ago both of these causes operated to condemn the series system. Mr. Parfitt has devised and patented a magnetic cut-out used in combination with a double system of positive mains and a common return; so that the failure of one lamp does not affect the lamps in series with it, but only that lamp, and that only temporarily, which is on the corresponding section. This will be clear from the diagram (Fig. 1), which shows the arrangement of lamps and magnetic cut-outs. It will be seen that the positive part of the circuit is divided into two branches, in each of which flows half the line current. Each lamp has in series with it the exciting coils of an electro-magnet, the resistance of which is equal to that of the lamp. Also a resistance is placed as a shunt to the lamp, one end of it being coupled to the line and the other disconnected from it, so long as the armature of the electro-magnet remains away from the magnet poles. The magnets are designed so that the normal lamp current will not lift their armature; but when a lamp breaks and the double current passes through the allied lamp, and consequently through the coils of its magnet, its armature is attracted, and closing the

Digitized by Google

circuit through the shunt resistance provides a by-pass of the same resistance as that of the broken lamp. If the second lamp fails as well, then the whole of the current passes through the magnet coils and leaves things otherwise unaffected.

The automatic cut-out is shown in elevation in Fig. 2. This cut-out is the distinctive feature of the system, the commercial success of which depends on its mechanical and electrical efficacy, whilst on the validity of the patent as a necessary and *exclusive* device depends the financial value of the property of the syndicate now offered to the public. The current enters by the wire A, passes through the coils B of the electro-magnet, and leaves the instrument at C. An armature D pivoted at E is attracted when an excess of current passes through the magnet coils, so that its free end F enters between two surfaces placing the binding-post C in connection with the binding-post G, to which the wire leading to the resistance to be introduced is connected. It will be noticed that when the end F of the armature is between the surfaces the current is divided, part of it continuing to flow through the lamp as heretofore and part flowing through the plate, binding-post G to the shunt resistance.

Mr. Parfitt's patent is No. 17,324 of 1891 (October 12th). Its claims are two in number, as follows :—

(1.) In series electric lighting, sub-dividing the main line into several branches through which the current flows, and which branches have their lamps arranged in them in groups and in series, the said branches being metallically connected together in pairs in order that an excess of current passing through one part of the branch shall be again equally divided before passing to the next lamps, substantially as described.

(2.) The employment of an automatic switch adapted to be operated when an excess of current passes, in order to allow part of the current to flow to the lamps whilst the other part flows to a resistance, substantially as described.

It may be doubted whether the device is the only one capable of fulfilling the conditions necessary for a successful incandescent series system. But we think it to be a fact that as yet no other device has been used for this purpose with even a fair

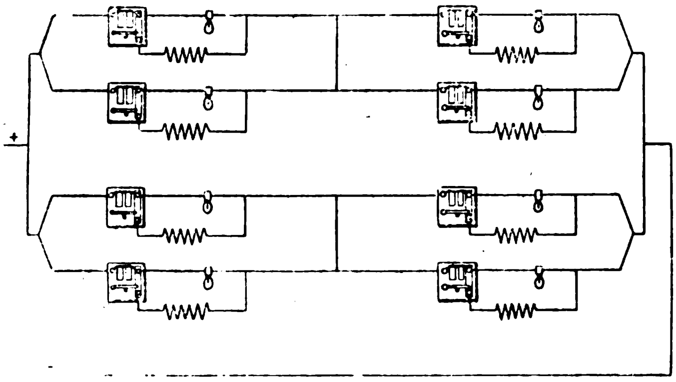

FIG 1.—Parfitt Series System of Lighting: Diagram of Circuit Arrangements.

degree of success, while the Parfitt system has been working without any failures from this cause for rather more than four years. If the Syndicate were content to rest their claims to public support upon this feature we think they would be wise. But, judging from a printed slip signed by Mr. E. Casper, one of the directors of the projected Company, copies of which were sent to the visitors, there is a tendency, perhaps unconscious, to go beyond this. There are in this document statements claiming that the Parfitt system of lighting is cheaper and superior to all others in respect to the cost of producing electricity, and especially in respect to fuel consumption. The following extract gives the gist of this circular :—"A salient proof of its practical importance is given by the fact that the public lighting of Keynsham and Kingswood (two suburbs of Bristol) *costs* [total] per unit less than 2¼d., whilst the average [total] of other towns is between 4d. and 5d. The cost of coal per unit at Bristol is 1·27d., against 0·325d. by Parfitt's system at Keynsham, *vide* the Board of Trade returns." The words "total," in brackets, are ours. We have inserted them because we were assured that the figure 2·25d. was the total cost of production, including depreciation.

The disingenuousness of this statement is apparent when we consider that the fuel consumption for Kingswood and Keynsham is based on the running of two compound engines worked at their most economic load practically throughout the time of supply, and that during the day the current is disconnected from the mains. In Bristol, as is well known, the capacity of the plant is far in excess of the present demand, and the average load factor is rendered still smaller by the compulsory continuous service. It should be noted also that no Board of Trade returns have been made by the syndicate. Mr. Parfitt told the visitors that the street lighting at Kingswood brought in a revenue of £650 per annum, while the *total* cost of production, including a sum equal to 7½ per cent. on the capital outlay for depreciation, was only £550, thus showing a clear profit of £100 per annum, whilst at Keynsham the public lighting realised £130 per annum, and the private lighting, at 6d. per unit by meter; or 17s. 6d. per 8-c.p. lamp by contract, brought in £195 for the same period. The working expenses for the latter station were not given, and, as the load factor is smaller than that at Kingswood, there is probably no profit at present; at least, we could not get information to that effect. In our judgment, and with all deference to Mr. Parfitt, it is courting financial disaster to supply local authorities at

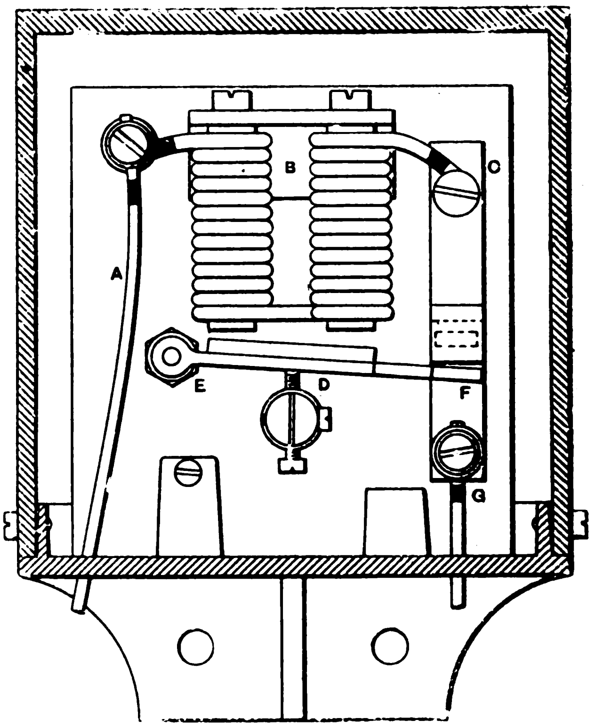

FIG. 2.—Parfitt Series System of Lighting: Elevation of Automatic Switch.

2·5d. per unit under the conditions obtaining at Kingswood and Keynsham. We appreciate the pluck of the originators of the lighting scheme, and we should be glad to see them face the inevitable, and charge a sum which will give them a fair chance of paying their way when the effects of depreciation make themselves fully felt.

Another point claimed by the promoters is the low cost of installation, and here we again join issue. It is, perhaps, true that the series system is the most economical as regards weight of copper for the given distribution of light, and as the mains are run on wooden posts, the outlay at the two places should not be large. We were informed that the total cost of the two installation, including freehold ground was just £10,000. But we are not sure that a high-pressure three-wire system, using 200-volt lamps, would be more costly. It would be certainly more convenient. We are also of opinion that the Board of Trade regulations will before long require *all* high-pressure electric light wires to be laid underground, in which case much of the advantage of a small cross-sectional area of copper would be lost; for it would be hardly worth while to go to the expense of laying underground such small wires as are used here, Nos. 12 and 14 S.W.G. In fact, series incandescent lighting appears to be suitable only for widely

Digitized by Google

distributed districts, in which an overhead system of distribution is permissible.

To come to practical points. At Kingswood seven miles of streets are lighted by three circuits, respectively 2, 2½ and 3 miles in length. The lamps are spaced roughly at distances of 60 yards, and are elevated at from 14ft. to 20ft. from the level of the road, according to their candle-power. The lamps vary from 100 c.p. in the High-street to 35 c.p. and 25 c.p. in the side roads. The 100-c.p. lamps are switched out at 11:30 p.m., and others of 16 c.p. are put in circuit. The smaller lamps are switched in before the larger ones are cut out, and so the continuity of the light is maintained. There are 150 lamps, of which 16 are of 100 c.p., 52 of 35 c.p., 80 of 25 c.p., and a few of 16 c.p. The indicated horse-power at full load is about 32. There is a penalty clause in the agreement of 10s. per lamp per night for all defective lamps, and it says much for the regularity of the supply, and also for the good working of the magnetic cut-outs, that the fines for the past year do not amount to more than £7, and these were largely due to bad lamps. The station plant comprises a compound Davey-Paxman horizontal engine, which drives by belting three dynamos, a dynamo and its exciter, giving 800 volts and 12 amperes, divided into three circuits of 3 amperes each, and a shunt-wound dynamo, giving 130 volts and 60 amperes, which is used for running the private lighting. There is a battery of 384 T.K.7 type E.P.S. cells, which forms a reserve against breakdowns, and is useful for testing purposes. The boiler is a 16-N.H.P. Davey-Paxman Economic type, working at 140lb. pressure. The mains which supply the high-pressure circuits are No. 14 S.W.G., and are insulated. They are carried by slings from steel bearer wires strung from insulators in the usual way. The low-pressure circuits are of bare copper, No. 12 S.W.G.

An ingenious device in connection with the magnetic cut-outs has been contrived by which part of the main current is made to return to the station from any defective lamp through the steel bearer wire, and as this has a constant resistance per mile run, the current passing through a suitably calibrated ammeter is a rough indication of the position of the defective lamp. The current can also be made to ring a bell to call the attention of the attendant.

At Keynsham the engine and boiler are of the same type, and of about the same power. But since the area is more confined, and the lighting is largely private, two 65-volt shunt dynamos are coupled in series, one giving 200 amperes and the other 130. There are nine circuits, totalling four miles in length, run from the terminals, those for street lighting being at 130 volts, and those for private lighting at 65 volts. There is a battery of 35 Crompton-Howell L 23 cells and 66 E.P.S. K 23 cells. The street lamps are 69 in number, 14 of 100 c.p. and 55 of 25 and 30 c.p. The private lighting circuits have an equivalent of 550 lamps of 8 c.p. wired, the average load being equal to about 125 lamps. The circumstances here are thus not so well adapted for displaying the Parfitt system, and the lighting is chiefly operated as a parallel system.

To conclude. The Parfitt system, though it certainly will not revolutionise electric lighting, is not without interest, as being an ingenious attempt to tackle village lighting—a singularly barren field whether for oil, gas, or electricity. As a technical journal there is no need for us to follow the financial press in its diatribes against the promotion environment of the proposed company: it is passing strange that those who have in their day swallowed so many camels should suddenly strain at this very small gnat.

ON THE ELECTRIFICATION OF AIR.*

BY LORD KELVIN, P.R.S.

Continuous observation of natural atmospheric electricity has given ample proof that cloudless air at moderate heights above the earth's surface, in all weathers, is electrified with very far from homogeneous distribution of electric density. Observing, at many times from May till September, 1859, with my portable electrometer on a free and open beach on the island of Arran, in ordinary fair weather at all hours of the day, I found the difference of potential between the earth and an insulated burning match at a height of 9ft. to vary from 200 to 400 volts, and even during light breezes from the east and north-east it went up to 3,000 or 4,000 volts. I never found the potential other than positive, if for brevity we call the earth's potential at the place zero. In perfectly clear weather I even observed the potential at the 9ft. height to vary from about 300 volts gradually to three or four times that amount, and gradually back again to nearly the same lower value in the course of about 2min. I inferred that these gradual variations must have been produced by electrified masses of air moving past the place of observation. I did not remark then, but I now see that the electricity in these moving masses of air must in all probability have been chiefly positive. Thinking of the subject now, we see that the gradual variations minute after minute through so wide a range as three or four to one, and not infrequently rising to 20 times the ordinary minimum, must have been due to positively electrified masses of air, within a few hundred feet of the place of observation, wafted along with the gentle winds, of 5ft. or 10ft. or 15ft. per second, which were blowing at the time. The two fundamental questions in respect to the atmospheric electricity of fair weather force themselves on our attention; first, what is the cause of the prevalent positive potential in the air near the earth, the earth's potential being called zero? Second, how comes the lower air to be electrified to different electric densities, whether positive or indicative, in different parts? Observations and laboratory experiments made within the last six or eight years, and particularly two remarkable discoveries made by Lenard, have contributed largely to answering the second of these questions. In an article "On the Electrification of Air by a Water Jet," by Magnus Maclean and Makita Goto, experiments were described showing air to be inactively electrified by a jet of water shot vertically down through it from a fine nozzle into a basin of water 60cm. below it. Lenard conclusively proved that the electrification was due chiefly, if not wholly, to the violent commotions of the drops impinging on the water surface of the receiving basin, and he found that the negative electrification of the air was greater when they were allowed to fall on a hard slab of any material thoroughly wetted by water than when they fell on a yielding surface of water several centimetres deep. Lenard made an independent experimental investigation in the physical laboratories of Heidelberg and Bonn, by which he learned that the seat of the negative electrification of the air electrified is the lacerated water at the foot of the fall, or at any rocks against which the water impinges, and not the multitudinous interfaces between air and water falling in drops through it.

It still seems worthy of searching inquiry to find electrification of air by water falling in drops through it, even though we now know that if there is any such electrification it is not the main cause of the great negative electrification of air which has been found in the neighbourhood of waterfalls. For this purpose an experiment has been recently made by Mr. Maclean, Mr. Galt, and myself. The apparatus we used consists of an electrometer connected with an insulated electric filter applied to test the electrification of air drawn from different parts of a tinned iron funnel, 187cm. long and 15cm. diameter, fixed in a vertical position with its lower end opened and its upper end closed, except a glass nozzle of 1·6mm. aperture admitting a jet of Glasgow supply water shot vertically down its axis. The electrical filter R (see Fig.), a simplified and improved form of that described in the *Proceedings* of the Royal Society, March 21st, consists of 12 circles of fine-wire gauze, rammed as closely as possible together in the middle of a piece of block tin pipe of 1cm. bore and 2cm. length. One end of it is stuck into one end of a perforation through a block of paraffin K, which supports it. The other end, G, of this perforation is connected by block tin pipe and indiarubber tube through bellows to one or other of two short outlet pipes, M and P, projecting over the large funnel.

We first applied an indiarubber pipe to draw air from the funnel at the upper outlet P, and made many experiments to test the electricity given by it to the receiving filter R under various conditions as to the water jet, the bellows being worked as uniformly as the operator could. When the water fell fairly through the funnel, with no drops striking it, and through 90cm. of air below its mouth, a small negative electrification of R was in every case observed. But when the funnel was slanted so that the whole shower of drops from the jet, or even a small part of it, struck the inside of the funnel, the negative electrification of R was largely increased. In a series of experiments made on March 25 we found 0·28 of a volt in 15 minutes with no obstruction to the shower, and 4·18 of a volt in 5 minutes with a metal plate held 3cm. or 4cm. below the mouth of the funnel, the air being drawn from the upper outlet P. Immediately after, with P closed and air drawn from the lower outlet M, but all other circumstances the same, we found 0·20 of a volt in 5 minutes with no obstruction, and 6·78 volts in 5 minutes with the metal plate held below the mouth as before.

These results confirm Lenard's conclusion that preponderatingly strong electrification is given to the air at place of violent impact

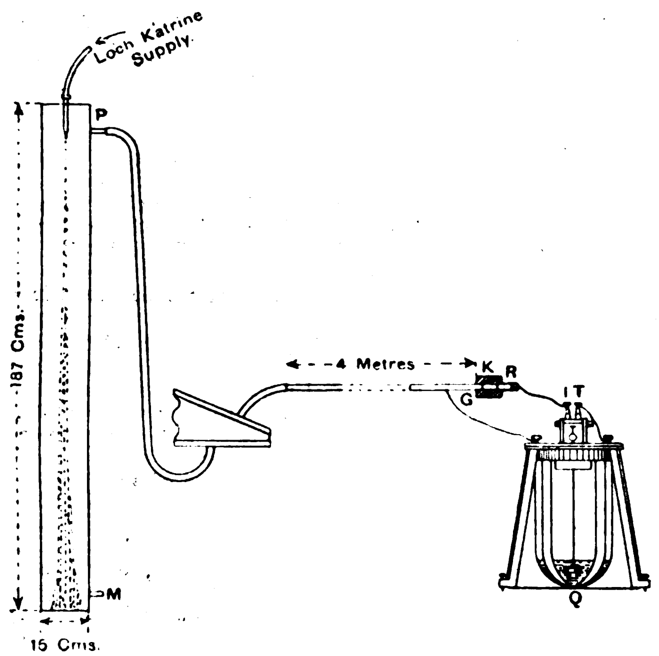
* Abstract of a Paper read before the Philosophical Society of Glasgow.

Digitized by Google

against a water surface or against a wet solid. But they do not prove that there is *no* electrification of air by drops of water falling through it. We always found in every trial decisive proof of negative electrification, though of comparatively small amount, when there was no obstruction to the shower. We intend to continue the investigation, with the shower falling freely down far enough from the mouth of the funnel to make quite sure that the air which we draw back from any part of the funnel is not sensibly affected by impact of the drops on anything below.

The other discovery of Lenard is that the negative electrification of air in his experiments with pure water is diminished greatly by very small quantities of common salt dissolved in it; that is, brought to nothing by 0·011 per cent.! That positive electrification is produced in the air when there is more than 0 011 per cent. of salt in the water, reaching a maximum with about 5 per cent. of salt, when the positive electrical effect is about equal to the negative effect observed with pure water, and falling to 14 per cent. of this amount when there is 25 per cent. of salt in the solution. Hence sea water, containing as it does about 3 per cent. of common salt, may be expected to give almost as strong a positive electrification to air as pure water would give of negative in similar circumstances as to commotion. Lenard infers that breaking waves of the sea must give negative electricity to the air over them; but finds a recorded observation of Exner, on the coast of Ceylon, showing the normal positive electric potential of the air to be notably increased by a storm at sea.

The strong positive electricity which I always found in Arran with an east wind, seemed at first to be an attribute of wind from



that quarter; but I soon found that in other localities east wind did not give any very notable augmentation, nor perhaps any augmentation at all, of the ordinary fair weather positive electric force; and for a long time I have had the impression that what I observed in this respect, on the sea beach at Brodrick Bay, in Arran, was really due to the 12 nautical miles of sea between it and the Ayrshire coast; and now it seems to me more probable than ever that this is the explanation, when we know from Lenard that the breaking waves must every one of them give some positive electricity to the air wherever a spherule of spray falls upon unbroken water.

From Lenard's investigation we now know that every drop of rain falling on the ground or on the sea, and every drop of fresh water spray of a breaking wave falling on a fresh water lake, sends negative electricity from the water surface to the air; and we know that every drop of salt water falling on the sea from breaking waves sends positive electricity into the air from the water surface. Lenard remarks that more than two-thirds of the earth's surface is sea, and suggests that breaking sea waves may give contributions of positive electricity to the air which may possibly preponderate over the negative electricity given to it from other sources, and may thus be the determining cause of the normal fair weather positive of natural atmospheric electricity. It has always seemed to me probable that the rain itself is the real restorer of the normal fair weather positive. Rain or snow, condensing out of the air high up in the clouds, must of itself, I believe, become positively electrified as it grows, and must leave positive electricity in the air from which it falls. Thus, rain falling from negatively electrified air would leave it less negatively electrified or non-electrified or positively electrified. Several times during the last 30 years I have made imperfect and unsuccessful attempts to verify this hypothesis by laboratory experiments; and it still remains unproved. But I found some degree of confirmation of it in Elster and Geitels' large and careful investigation of the electricity produced in an insulated basin by rain or snow falling into it.

Air blown from an uninsulated tube so as to rise in bubbles through pure water in an insulated vessel, and carried through an insulated pipe to the electric receiving filter, of which I have already told you, gives negative electricity to the filter; while with a small quantity of salt dissolved in the water it gives positive electricity. There can be no doubt that these results are due to the same physical cause as Lenard's negative and positive electrification of air by the impact of drops of fresh water or of salt water on a surface of water or wet solid.

MUNICIPAL ELECTRIC LIGHTING LOANS.

At the usual weekly meeting of the London County Council, held last Tuesday at the County Hall, Spring-gardens, the Finance Committee submitted an important report relative to the period for which loans for electric lighting purposes should be granted. The report was based on an application from the St. Pancras Vestry for a loan of £14,600, for the purposes of electric lighting. The Committee reported on the subject on July 17th last year, and recommended, consequent on the Council having granted 42 years to the Hampstead Vestry for the repayment of a similar loan, that sanction should be given the St. Pancras Vestry borrowing £14,300, and a similar term should be allowed for repayment. The Treasury, however, on being notified of the above terms, took exception to the period for repayment as being disproportionate to the life of the works. Communications there upon took place with the Treasury, and eventually an agreement was arrived at to the effect that the maximum periods for repayment of all loans for the initial cost of electric lighting undertakings should be as follows:—For land, building, culverts, bare copper mains, and royalty licences relating to such purposes 50 years, and for all other purposes 20 years. That agreement was fully set out to the Council on November 20th last, and the Council confirmed it, as applicable to all future loans for electric lighting. If, however, those terms were to be applied to the loans for electric lighting already made to the St. Pancras Vestry, it would be necessary to restrict the period for repayment of the loan now asked for to 20 years, as the previous loans had been for longer periods. The Vestry having been informed of that, asked the Council whether they would give them permission to borrow the money elsewhere. The Committee reported to the Council on that letter, to the effect that they must adhere to the principle embodied in the agreement with the Treasury. The Council, however, considered the matter on January 29th, and the recommendation was then withdrawn, on the implied understanding that a further representation should be made to the Treasury. The Committee had now to report that their lordships had approved of an alternative period of repayment, viz., 42 years, for the whole initial cost, provided that no further loan should be raised to defray the cost of renewing any works, plant, machinery or appliances which might require renewal during the currency of the original loan. That they considered to be a fair condition, and one which the Council should accept. The vestries would thus be able to borrow for 50 years for land, buildings, culverts and mains, and 20 years for other purposes as stated above, with right of borrowing for any necessary renewals of plant at the expiration of the 20 years, or of having an all round period of 42 years for the entire cost of installation, with a restriction as to further borrowing to supply any necessary replacement of plant and machinery until the amount raised has been paid off; any plant requiring to be renewed in the interim being defrayed out of a sinking fund for renewals or from maintenance account. The Vestry of St. Pancras, having been informed of the Treasury decision, had expressed their satisfaction therewith and willingness to accept the loan of £14,300, with repayment in 42 years on the condition mentioned. As the matter was of interest and importance to the Council and the Local Authorities generally, the Committee had directed the correspondence to be printed and attached to the report for future reference.

Mr. ROBERTS inquired whether the parish of Islington would be placed upon the same terms as St. Pancras in regard to the loan which they applied for at the same time as the St. Pancras Vestry.

Mr. A. HOARE, Chairman of the Committee, replied that St. Pancras had accepted the terms of the Committee without reservation; but the Islington Vestry had made certain reservations which made it necessary to enter into further correspondence with them. He had no doubt that it

Digitized by Google

would be the pleasure of the Finance Committee to treat all vestries in the same manner.

Mr. BEACHCROFT said that as the recommendation involved such an important question of principle, he hoped the Chairman would postpone it for a week.

Mr. WESTACOTT, as representing St. Pancras, hoped that the Chairman would not consent to the postponement of the report, as it had been before the Council now for nearly 12 months.

Mr. CAMPBELL characterised the proposed period for repayment as partaking of the nature of dishonest finance, and he maintained that it was wrong to burden the future ratepayer for the benefit of the present generation. He proposed that the loan be granted for 20 years.—The amendment met with no seconder, and it was therefore negatived, and the recommendation of the Committee to grant the St. Pancras Loan was agreed to.

PARLIAMENTARY INTELLIGENCE.

SELECT COMMITTEE ON THE TELEPHONE SYSTEM.

The Select Committee sat again on Friday, the Postmaster-General presiding, when

Mr. A. D. PROVAND, M.P. for Glasgow, gave evidence as to the trunk-wire charges in Scotland. He said that the trunk-wire system had been more fully developed in Scotland than in England; but under the Agreement with the Post Office the rates (of which he handed in a table containing 2,330 inter-town rates) would be very much increased, because at present the mileage scales of the Company were less than those of the Post Office.

The CHAIRMAN pointed out that there was no reference to trunk wire charges in the Agreement.

The WITNESS said that it had been stated many a time that the Agreement was carrying out the Treasury Minute, and the rates which the Post Office intended to charge were contained in the Treasury Minute. If the Post Office did not intend to charge those rates, and the Postmaster-General would say so, that, of course, would make some difference; but the scope and effect of the Agreement would make the trunk-wire charges in Scotland enormously higher than they were at present.

The CHAIRMAN: Would you point out any clause in the Agreement that bears out that statement?

The WITNESS admitted that it was not to be found in the Agreement, but maintained that that would be its result.

The CHAIRMAN: I think you may take it from me that there is nothing in the Agreement which embodies these trunk-wire charges; the charges which are indicated in the Treasury Minute are subject to revision and Parliamentary control, and there is nothing in the Agreement embodying them, although they are charges which the Department at present proposes to make.

The WITNESS proceeded to compare the table of mileage charges of the Post Office with that of the National Telephone Company. Up to 20 miles the Company and the Postmaster charge the same; from 20 to 25 miles the Postmaster would charge twice as much as the Company; from 25 to 40 miles the charge would again be the same, but from 40 to 50 miles the Postmaster would charge twice as much as the Company; from 50 to 75 miles the Postmaster would charge one-third more than the Telephone Company; from 70 to 80 miles the charge would be the same; from 80 to 100 miles the Postmaster would charge 50 per cent. more than the Company; from 100 to 120 miles both charge the same; from 120 to 125 miles the Postmaster would charge one-fourth more than the Company; from 125 to 150 miles again the charge was alike; and from 150 to 160 miles the Company for the first time charged more than the Postmaster by one-fifth (2s. 6d. against 2s.); from 160 to 175 miles the charge would be the same; and from 200 miles upwards there would be on some distances a higher charge by the Company than by the Post Office. The increased charge made by the Postmaster over the Company was not entirely represented by the difference of rates he had quoted, because the Company at present did not charge for their inter-town service as high as they might charge according to their scale. Of the 2,330 rates which they quoted, 349 were at 3d; 683 at 6d., 727 at 9d., 414 at 1s., 145 at 1s. 6d., 9 at 2s. 6d., and 3 at 3s. The rates for short distances by the Company were much cheaper than would be charged by the Postmaster, and as most messages were for shorter distances, the increased charge would be a great hardship.

The CHAIRMAN pointed out that the Company's rates were for subscribers only, and that non-subscribers were charged double rates by the Company, whereas the Post Office would charge subscribers and non-subscribers equal rates.

The WITNESS said that the Post Office would never make anything at all of the non-subscribers. He objected to be charged an excessive rate in order that the Post Office might make a gift to other people who neither valued it nor used it. If the Post Office intended to do so, then it was another of the gross injustices which the Post Office practised upon the Committee. (This statement was received with loud laughter, in which the members of the Committee joined.)

The CHAIRMAN put instances to the Witness of the charge made by the Company in Scotland being 1s., while the Post Office charged 3d. or 6d. If those were facts, and he asked the Witness to accept it from him that they were, and they were for short distances, then they were entirely inconsistent with the statement which the Witness had made.

The WITNESS said he was not aware of those facts, and the information had not been supplied to him when he had asked questions in the House on the subject. He went on to complain of the inefficient character of the service in Glasgow, which, he suggested, was owing to the single-wire system, and to advocate the abolition of the terminal charges.

In reply to Sir J. Fergusson, he said that it was the case that the prices were raised in some instances, because otherwise, if the Government took over the telephone system, the charges would be less than for telegrams. Replying to further questions, he said that the terminal charges would mostly affect the inter-town communication, but he did not think they would afford a serious bar to the establishment of municipal systems.

Mr. W. H. PREECE, chief electrician to the Post Office, was recalled, and, in reply to the Chairman, described the various instruments used in telephonic communication. The first, he said, was the receiver, and there was very little difference between the style of instrument now in use and that which was used when the system was first brought over to England. The transmitter was that part of the instrument which converted the wave sounds of the air, and electrically conveyed the message to the receiver at the other end. The transmitter had passed through several stages of improvements, and had not yet approached perfection, for every day they were receiving suggestions for improvements. Those instruments were connected together with two wires, forming a metallic circuit, which wires were best twisted about each other. The use of one wire only made a defective system, led to innumerable troubles, caused imperfect and in fact was the principal cause of the great unpopularity of the telephone. In the Post Office they had always used the metallic circuit by means of the twin-wire system, but the introducers of the telephone system in England and America, for the sake of economy, used the single wire. The twin-wire system was being introduced rapidly into England; it was almost general in the United States, and over the Continent very largely. Proceeding to describe the switchboard, he said it derived its name really from the railway people. It was the machinery that shifted or directed the current from one circuit to another, and the operation was a very simple one. The switchboards had taken different forms. The members of the Committee saw on the previous day in Lime-street that which was called the panel or upright form, and in Gerard-street a modification of it which was called the table form. The one great advance or improvement which had been made in the switchboard was the introduction of the multiple switch, which gave every operator in the exchange complete command over every subscriber in the exchange, so that if they had 10,000 subscribers concentrated on one exchange every single operator would have under her control everyone of those 10,000 subscribers. But the introduction of the multiple switch, while it had facilitated very much the work of the exchange, had brought with it certain difficulties, one of which arose from the tremendous multiplicity of holes, or jacks, as they were called. The largest system had got about 6,000 subscribers; there was one in Paris, one in New York, and he was not quite sure whether the Telephone Company here were not fixing one. A switchboard for 10,000 subscribers meant 500,000 jacks, and everyone of those jacks involved some four or five joints, so that the fitting up of a switchboard for 10,000 subscribers meant three or four million joints being made; but the result would be that the whole of the 10,000 subscribers could be placed under the control of every operator.

The CHAIRMAN: Of course, the 10,000 subscribers would be divided up among a large number of operators, but by the multiple system each operator would have the means of communicating with the jack belonging to each subscriber?

The WITNESS: Yes; there would be 200 or 250 operators and two or three in charge of a section, there being 20 sections. The table system at once swept away half the number of jacks, so that instead of having half a-million jacks there would be only 250,000. In Chicago and one or two other places they were now trying what was called the divided board, which reduced the number of jacks to one-fifth, instead of half, and the divided board was extremely favourably reported upon. It was being worked out principally in Chicago. The department of the Post Office was constantly on the watch for improvements, and he had not only visited America and seen what was going on, but was in constant correspondence with the telephone companies there, and was kept fully alive as to all the progress that was made and the experiments that were going on. The Witness then proceeded to describe the operations which took place when one subscriber wished to have communication with another. Each subscriber must attract the attention of the exchange operator, and in turn the exchange operator must be able to call each local operator. That was generally done by raising an indicator at the exchange and in the subscriber's house by a wave of the hand. In the Post Office they had introduced a peculiar system which had attracted a great deal of attention, and which had been the subject of a Paper in the United States, where they were now commencing to introduce it. Instead of relying on the ringing of bells they had produced a system of individual signals which did not depend on the sound at all. There was a little indicator which moved, and that indicator gave different signals, which he would explain to the Committee. But first of all he wished to call their attention to another modification, known as the Law system of call, which was produced in Glasgow, and was now in work there. There was a call wire apart altogether from the talking wire, which went to every subscriber's house. At every station there was an operator who had always got a telephone at her head; the subscriber had to go to the talking wire, and say "I want No. 30," which, being heard by the operator, the operator then switched him on. Experts on the question were very much at variance as to the merits of the various systems of call. As the representative of the Post Office he considered that which they had in operation the best service in the world, but of course he might be prejudiced in that respect. He thought the Law system pretty near perfection, though it had not been received with favour in the United States. He liked the system, because it gave automatically and instantaneously notice to the operators that the wire was engaged or disengaged, and that the conversation was over as soon as it was over. The subscriber simply lifted the telephone off the hook—that was the signal; there was no ringing at all; the operator received the

Digitized by Google

instructions and could see whether the line was engaged or disengaged; conversation would commence, and when it ceased the mere act of putting the telephone on the hook was an indication that the conversation was over. It was objected to the system that it involved the use of batteries, but they found in the Post Office that the cost of the batteries was so small that it did not even appear in their accounts.

Sir JULIAN GOLDSMID: Really, if the operator could see when the wire was being used and when it was not being used, there would be great saving of time?

The WITNESS: Yes; that was the object of the signal. In the American system and in the system used principally by the Telephone Company in England, which was called the busy test system, when the operator touched the instrument it gave a click if it was engaged, which the operator knew to be the signal. That took up about one-half of the operator's time, which was saved by the Law system as against the busy test system. Then changes had taken place with regard to the material for the conductors. At first the conductors were iron, but now they were of copper or sometimes bronze. Iron conductors were inherently bad and absolutely subversive of clear speech. There was some reaction between the current and the matters generally found in the earth which seemed to absorb a good deal of the energy that produced clear speech, and by speaking through an iron wire the voice became blurred, and it was difficult to distinguish one man's voice from another's.

Sir JULIAN GOLDSMID: Is there a great quantity of iron wire still used in England?

The WITNESS: No; a very small quantity. He doubted if there was any, with the exception of the telephones used upon the railways. He did not think the Telephone Company had any, and the Post Office now never put up any iron wire. Replying to the Chairman as to the comparative merits of underground and overhead wires, he said there was an advantage in having trunk wires overhead, and there was no disadvantage in having local wires underground. The reason was that an underground wire, like a cable, retarded the electric current; just like iron, it absorbed those minute electrical waves which enabled them to distinguish between one voice and another, and, in fact, it checked the speed of the current. It was not unlike speaking through a long speaking tube when the voice became blurred at the entrance. Where they had the wires underground it spoiled the articulation and the individual identification. That was due to an electrical quality which might be called the capacity of the wire for retaining its discharge. They could measure the capacity of every wire, and knew how to reduce it, but they could not remove it altogether. If they had to speak through from Plymouth, Leeds, Carlisle, Birmingham, and Bristol, and if all those places had underground wires, the sum of all those short lengths underground would retard the current. Taking each one by itself, its effect was not sufficiently large to blur the voice, but when they took the whole of them together it was sufficient to produce that result. For long distances the overhead system was distinctly superior to the underground, and it was absolutely essential that the wires should be taken overhead. There was not much difference in the cost. The London to Paris telephone, which was one of the best, was wholly overground, with the exception of the cable across the Channel. They were very rapidly reducing the capacity of underground wires which led to retardation, and in America they had succeeded in reducing it to one-fourth. The coating of the wires with paper had certainly good effects, and when applied to cables with a great number of wires it brought the price of the underground work so low that the difference between the underground work and overhead virtually disappeared. It reduced the price per mile per circuit for a double circuit of line of pipes filled with conductors to £18, as against £15 or £16 overhead, but it was only when they carried a great number of wires that there was great economy. It really came to this: that while it was impossible to put underground wires where they had only six or eight or ten wires, owing to the price, when they came to 100 or 200 wires it was cheaper to go underground than over ground.

The CHAIRMAN: Have you had sufficient use of paper, as compared with gutta-percha, to say what the life of the paper is?

The WITNESS: Yes. They had had quite 10 years' experience of using paper. It was adopted five years ago generally in the States, and he had experience himself of about five years, using it exclusively for trunk wires; and he had absolute confidence in its durability. There was not a single instance, either here or in the United States, of failure. Where the paper was kept dry it did not decay, and the whole secret of the success of the use of paper was in keeping it dry. Placed in lead pipes, hermetically closed, it would answer, but if water got in, it would decay, and break down the circuit.

The CHAIRMAN: Is it as durable as gutta-percha?

The WITNESS: More so; if the paper can be kept dry it will last for a thousand years.

In further reply to the Chairman, the WITNESS said that the twin-wire system was equally applicable to the overhead system as the single wire, but he agreed with the opinion expressed by the previous witness, that it was not possible to make a satisfactory metallic circuit except with twin wires.

The CHAIRMAN: The Committee have heard that the Department are taking over on July 1st the trunk-wire system of the Telephone Company. Would you describe the general system of trunk wires and the action the Department have taken since the Agreement was entered into between the parties.

The WITNESS first described, by means of a map, the system of trunk wires at present held by the Post Office, and stated that by next Tuesday it would be possible to complete another line from Leeds to London, which would give them a continuous line from London to Glasgow. As Leeds was the most central town in the country it was essential that it should be made the exchange for the trunk-wire system, and all trunk lines would centre at Leeds. The lines had been constructed quite up to date, at a cost of £800 per mile out of the half million voted by Parliament in 1892, and he had every reason to believe that the speaking through them would be as perfect as could be. They were also constructing a line from London to Salisbury, Southampton and Portsmouth, and to Bristol, which would connect the Plymouth and Exeter lines with Bristol, Southampton and Portsmouth. There was another line to Ipswich and Colchester, which they proposed to extend. They had already spoken from the outskirts of Hampstead (really from London) to Belfast and Dublin, and between London and Belfast the speaking was quite as good as it was between the City and Westminster. The officers of the Department had spoken from Plymouth through Bristol, Birmingham, Leeds and Glasgow, to Belfast, a distance of about 1,700 miles.

The CHAIRMAN: Is that a record performance as far as you know?

The WITNESS said that it certainly was on this side of the Atlantic; but he thought they had exceeded it on the other side. He had himself every confidence that there would be no difficulty whatever in every principal town in the country speaking perfectly easily with any other town, and more than that, he believed that the telephone would be enormously used, and that in about twelve months or two years there would be great demand for it. In the present year they intended to complete the system between London, Birmingham and Warwick to Liverpool. Speaking of the increase of telephone business in the United States, he said that between his two visits in 1884 and 1894 there had been the following advance. In 1884 the miles of wire were 115,000, in 1893, 444,000, and this year 557,000. The telephone service of America was entirely in the hands of private companies. In 1884 the miles of underground wire were nil; in 1893 there were 148,000 miles, and at the commencement of this year there were 325,000 miles. The telephones in use in 1884 were 325,000, and in 1895, 582,000. In America they called the receiver one instrument and the transmitter another instrument, so that to draw a comparison in the use of the telephone in America, that number should be divided by two, which would give 291,000 telephonists who now used it in America. In 1884 there were 123,000 subcribers, in 1893, 232,000, and now the number must be about 280,000. Everything had grown in the same ratio except the exchanges, the reason being that they were more centralised, there being a larger number of subscribers to each exchange. As showing the enormous use made of the telephone in America, he mentioned that on one day in Chicago there were 153,807 calls made and answered, and 307,000 persons were placed in communication with each other through 15 exchanges. In Glasgow and Liverpool it was not unusual to have two or three telephones working side by side, but in Chicago they had as many as six. Referring next to the extension and development of the telephone system in France, he said that on March 11th last he visited the Paris exchange, and found that a very considerable growth of business had taken place since 1889, when the business of the telephone company was transferred to the State, the total number of subscribers to the State telephones being now 28,108. At the time that the transfer was effected the business at once increased, and the subscription was reduced from £22 to £16. He did not know the terms on which the telephones were transferred in France, but it was invariably an underground service. There was a peculiarity about the system there, that they had enormous underground sewers along which the wires were carried without any disturbance of the streets; but the objections which he had mentioned to an underground system would equally apply to subways of that kind.

Sir JULIAN GOLDSMID: The cost would be a little less, would it not, of putting them in the subways?

The WITNESS: Yes. He next described the operations in the exchange of enabling subscribers to communicate over the local, junction, and trunk wires, and produced a chart which, by means of curves, showed how the work was spread over the different hours of the day. This showed that very little was done before 9 in the morning, and that from 11 to half-past 11 in the morning, and at 3 in the afternoon, there was always a large number of calls. The whole work of an exchange was concentrated in a few hours of the day, and in the early morning and at night there was nothing whatever done.

The CHAIRMAN: Is that the experience of the Post Office with the London and Paris telephone?

The WITNESS said that that would not apply so much to that service, because it was used so much at night for Press purposes. Speaking further of the operations in the exchange, he said that to place a subscriber in communication with his local correspondent involved three distinct operations, and the time occupied by them depended not only on the skill of the operator, but a great deal more on the attention of the subscriber. Half the troubles in telephone working were really due to the subscriber, and not to exchange operations. When they had to use the junction wire the number of complete operations was six, which meant that there was more delay in getting through. The trunk wire working involved, when it was through one exchange, 12 complete operations, through two exchanges 16 operations, and still more through three exchanges. The work, however, was done much more rapidly when the Law system was used, and although there might be 12 operations there was no reason why the time occupied should be more than was occupied in local working. He had a letter from the United States which said: "We are now certainly showing that it is just as easy to trunk a message as it is to make direct connection."

The CHAIRMAN: Is that partly due to the fact that in getting through an exchange on the trunk wire the operator is communicating with another skilled operator?

The WITNESS said that no doubt it was so. In England, if anything went wrong, the subscribers grumbled and growled, but did not do their best to assist the Company or the Post Office, while in America they looked upon themselves as part and parcel of the system, and all did their best to assist the Company. In any conceivable system there must be delays in getting through in the busy time of the day. If competing systems were established in the same area, that would mean an increased number of

Digitized by Google

connections, and there must be increased delay. The general efficiency of the service would be injured, for the fewer the operations the better the work was done. The daily calls per circuit varied very much. The average per day over the whole of the United States in 1893 was 8·03, but at Chicago it reached as many as 34 at one exchange. At Boston the average was formerly 8·45, but now was 12·6; in Berlin in 1884 it was 12, and in Paris 5.

Sir JULIAN GOLDSMID: Berlin is on the single-wire system, is it not?

The WITNESS said he could not answer that. They had some peculiar system at work there which he did not quite understand. He was not quite sure that it was single-wire pure and simple, but was inclined to say that it was some combination. The number of lines per operator also varied very much on different systems at different places; but at an exchange, say, of 4,000 subscribers, it ought not to average more than for local work 50, for junction work 10, and for trunk work 5. With the view of showing that the larger the exchange the greater the number of talks per subscriber, and that the cost of working a large exchange was thereby increased, he quoted the following figures from the United States:—

Town.	Talks per day for each subscriber.	Customers per operator.	No. of subscribers.
Buffalo	6·0	100	2,240
Boston	12·6	75	3,545
New York	15·0	50	4,500

The increase in the number of operators was a very important element in the cost of working. At Buffalo the charge was made of an annual subscription and toll rate; there was an installation charge of $70, which covered the first 500 messages, and after that they paid 8c. a message of five minutes. At Boston the rate was $160, or £32; and in New York the subscription was $240, or nearly £50 a year, so that a larger number of subscribers was followed by a larger subscription in the case of those three towns, but he thought that was due to local circumstances altogether apart from the size of the exchange. The cost of fitting up an exchange with the multiple switchboard increased as the square to the number of subscribers. For instance, if they had a multiple board for 2,000 subscribers, and they doubled the number of the subscribers to 4,000, the cost of the switchboard would not be twice as much, but four times. It was that growth which rendered the multiple switchboard so expensive.

Mr. BENN: Is that the reason they gave up the multiple board in Chicago?

The WITNESS said he thought that must be the reason.

The CHAIRMAN: Does that fact make comparison between the charge for London and towns in Scotland somewhat inappropriate?

The WITNESS said he thought it ought to be taken into serious consideration. It was important that the Committee should take into account that whatever might be the annual rental, the working expenses must increase with the number of subscribers, and therefore that the balance between the revenue and the working cost must diminish; so that if the rental was too low and the number of subscribers too many, the working expenses would exceed the revenue, and rates would have to be increased. The average engineering expenses per subscriber was about £3 per annum; his estimate for an underground system for London was £55 per subscriber, and for the provinces £45. When Mr. Lamb was before the Committee he promised to put in a schedule of tariffs, &c., in other countries, and he had prepared a schedule (which the Witness handed in to the Committee) giving information with regard to Austria, Belgium, France, Germany, Hungary, Italy, Norway, Sweden, Switzerland, and the United States. It gave the fact whether the telephone was in the hands of public bodies or private companies; it described the system in use (and he saw that he put down a single wire for Berlin, but the Witness was not certain that Mr. Lamb was right); the area covered; the number of subscribers; the terms of subscription; statistics of profit and capital and trunk wire charges. He pointed out that there were three distinct bases of charge: first, fixed annual rental with unlimited service; second, a smaller annual rental with a limited service, and tolls for extra talks; and third, the system of charging tolls for everything, without any annual subscription. He read a letter from the Director-General of the Swedish system, stating that they were introducing, with considerable success, a system of charge measured by the amount of use made by each individual subscriber. In the first place they had an initial minimum, after which the subscriber paid a certain amount per message, on similar lines to the Buffalo system of charges, and the new plan seemed to take. One remarkable fact about Buffalo was that the number of calls per day had not increased, and now it was the lowest in the United States, which tended to show that the toll system took away the desire of subscribers to ask silly questions.

Replying to Sir James Fergusson, the WITNESS said that when the Agreement between the Post Office and the Company came into full working order he anticipated a great development of telephonic communication in this country. As to the question of having competing systems in London, there would be the difficulty of laying additional pipes under the streets, but that would not be insurmountable. There would, however, be enormous difficulty encountered in regard to way-leaves.

At the sitting of the Select Committee on Tuesday Mr. Arnold Morley again presided, and the examination of Mr. Preece was resumed. He described various attempts which had been made to do away with manual labour at the exchanges by electrical automatic switches, and especially a device which he saw at work in Brussels some years ago, and which was on exhibition at Chicago, by which an electric light indicated when the conversation commenced and ceased. Those devices were, however, based upon the assumption that the line was always in working order, always disengaged, and that the subscriber was always present. Such a system could only be used in very small exchanges, and would not be applicable to a large exchange like that of London.

Sir J. FERGUSSON: But, surely, you would be the last to say that it was impossible to apply such a system to London?

The WITNESS replied that the word "impossible" did not occur in the vocabulary of the electrician. Quoting towns in the United States in which, though the charges were high, the number of subscribers to the population was large, he said that he accounted for it by the fact that the telephone was essential to the conduct of business in the States. The habits of the people, the methods of locomotion, the temperature and climatic conditions, made it almost essential to them that they should conduct their business indoors. Referring to the toll system of charge now being adopted in Sweden, he said that it did not unduly check the use of the telephone; but he was rather an advocate for the combined system of a small rental and a small charge as toll. It would check the unnecessary use of the telephone, and he insisted that the intelligent use of the system was an important factor in its success. That was so much recognised in the States that not only did they look after the education of the staff, but had inspectors who went about to instruct the public in the use of the telephone. They also encouraged the subscribers to visit the exchange and see the work there, so that they might be able to grasp the working of the whole system.

The CHAIRMAN: Do you think there is need in this country for educational work of this kind?

The WITNESS said there was immense need for it. The Committee had had plenty of evidence from users of telephones, and if some of the witnesses who had appeared before the Committee had received such education he thought they would not have given such evidence. Asked to give his opinion upon the question of the municipalisation of telephones, he said he had five or six reasons against municipalisation. First, a public body like a town council would be at a disadvantage in conducting what to them would be a growing speculative and comparatively new industry, while they would not have that accumulation of experience which was necessary to maintain high efficiency. Secondly, high efficiency could only be maintained when the service paid. The active and energetic opposition of a determined company like the National Telephone Company, who could under-cut prices in one part of their system to maintain their position, would certainly prevent the possibility of local success, while at the same time they would penalise the other parts of the system by maintaining high prices in order to recoup the loss in the district where they were competing. Thirdly, financial failure on the part of a municipal system would speedily secure the opposition of the labouring and employed classes of the ratepayers who did not benefit by the use of the telephone, and who formed the majority, and were, therefore, the masters of the situation. Fourthly, high efficiency depended essentially on skilled labour and effective supervision. Small municipalities could not afford to pay high salaries to secure or maintain the services of highly-skilled technical men, nor had they the experience to develop effectually the education of the men they employed. They could not compete with the Post Office in its prospects of promotion and of pension on retirement. Fifthly, that in a small municipality (and he was dealing more with small municipalities than with large ones) not managed by skilled men, the service would be irregular. There was no difficulty in arranging for a local subscriber on one system to speak to another subscriber on another system in the same town, but that could not be done commercially where there were different practices, and where there was ill-feeling and determined opposition. In any case it would lead to additional switch operations, and consequent delay and loss of efficiency. He had a return showing the time occupied at one of the most prominent exchanges in New York, where it appeared that the extra time per exchange was over a minute, so it really meant that the insertion of each extra exchange meant a minute's delay between a subscriber in one area and a subscriber in another area. He wished further to point out that a perfect trunk service could be obtained only on one uniform system, and with one staff. Every additional system meant enhanced expense, divided responsibilities accumulated difficulties, and serious delays. Centralisation of membership. in one central spot like London secured the advantage and benefit of the widest experience; it encouraged experiment and observation, and prevented the repetition of errors; it checked the exercise of individual idiosyncracies; it enforced technical education, and implied the highest efficiency. Those ideas were carried out by the system as now adopted in England as well as by the Bell Telephone Company in the United States. Municipalities, however, might do much for the development of the telephone by providing subways and conduits, and facilitating the acquisition of way leaves, and generally in assisting the conduct of the business under proper control and supervision.

The CHAIRMAN: Would most, if not all these reasons apply equally to competition by private companies in the same area?

The WITNESS: They would. The question of way leaves was a very serious one, and was growing more and more serious every day. The Post Office was in the position that it was subject to law and the regulations of an Act of Parliament, but there were many wires which were run up without law. Cheapside, for instance, was one mass of wires, and he believed $\frac{99}{100}$ths of those wires belonged to the Telephone Company. The Post Office failed to get way leaves to King's Cross and St. Pancras for its Newcastle wires, and they were everywhere troubled with the difficulty that owners objected to their property being trespassed over and the roofs damaged. At New York there was a company which constructed a subway and let out space in it for telephone wires, but they charged an exorbitant rent for the use of it. As to the extension of the telephone in rural districts, that could be encouraged to a large extent by district councils giving the guarantee which was necessary to meet the demands of the Treasury. That was done to a large extent in some parts of Wales, where several small offices had

Digitized by Google

been opened under guarantee by the District Council; but, as a rule, the rural people said they could communicate cheaper by telegraph than by telephone. The present number of telephones in use under the Post Office was: Exchange and call offices, 1,900; private wires, 3,000; public offices worked by telephone, 680; lifeboat stations and coastguard stations, 354; lighthouses, 39; lightships, 80; permanent wires, 1,025; making a total of 7,006 telephones worked on the Post Office system. He advocated an imperial monopoly for the postal, telegraph, and telephone services alike, because it secured uniformity, undivided responsibility, popular supervision, and public control, which meant not only the highest efficiency, but the greatest economy. The mail was quick, the telegraph was quicker, but the telephone was instantaneous, and they did not have to wait for an answer.

By Mr. GRANT LAWSON: Competing systems would be difficult to connect so as to be commercially successful. There would be the difficulty that subscribers would not know where to address their complaints, and there would also be the difficulty connected with having an innumerable list of subscribers. If there were three sets of subscribers—one to the Post Office, another to the National Telephone Company, and a third to a local company—each company would have to keep full lists of all three sets of subscribers.

By Mr. TULLY: He was not aware that the National Telephone Company sent round inspectors to instruct the people in the use of the telephone. In one instance, at Plymouth, the Company had succeeded in ousting the Post Office, and if they succeeded in doing that they would certainly succeed in ousting a municipal body. The conduct of telephone business was on a totally different footing to the supply of gas, water, tramways, and electric light by a municipality, because those matters were confined to the local areas, whereas the telephonic communication went far outside the local area.

Mr. TULLY: Supposing the municipality had a licence, and their system succeeded, would it not be better, when the State came to take over the telephones, that they should have the choice of taking over the better system of the two?

The WITNESS: That is a question of policy upon which I cannot give an opinion.

Mr. BENN cross-examined the Witness at some length as to his reasons for objecting to municipal telephones, and the Witness further urged that the Town Council being subject to election every three years prevented any continuity of policy; the fact that Parliament was also subject to re-election had not had any effect upon the Post Office policy. He did not know of any other way by which a municipality could get a cheaper telephone service, except by competition, unless by the intervention of the Postmaster-General. He understood that the new Telephone Company proposed to supply London at a lower price, but he could not accept the figures given in their prospectus. If they did not agree with his own figures he should say that they would probably be wrong. As to the letter which he had put in by the Director-General of the system at Switzerland he said he would not repudiate it, but he did not support it. If a municipality was willing to incur a loss there was no doubt that by obtaining a cheap service they would benefit those using the telephones. Asked what the Government would do in 1911, when the Agreement came to an end, he said it was too early to predicate what would occur at that time.

Mr. BENN: But we have to face that and to see what the effect of this Agreement would be upon the ratepayers of the country.

The WITNESS said those were questions of policy into which he could not go. He supposed they would either buy up the telephone companies or start a system of their own.

In reply to the Solicitor-General as to the circumstances under which the Post Office were ousted from Plymouth by the National Telephone Company, the WITNESS stated that the system was established by the Post Office there at the request of 40 subscribers. The Telephone Company, jealous of their starting, aided and abetted by one or two active men in Plymouth, went down there and started an opposition exchange; they went to all the Post Office subscribers and gave them telephones for nothing, and when the Agreement with the Post Office expired they gave up their telephones, and so continued to work on the Telephone Company's exchange. The Post Office had their hands tied by the Treasury, and so could not combat such competition.

Replying to Lord Stanley, he said he believed the National Telephone Company was doing its best to render its service as efficient as it could be made, and he was perfectly satisfied if in 1911 the Post Office took over that system it would be with first-class materials and everything up to date.

Mr. SNAPE stated that at Liverpool they had provided for 6,000 subscribers, had a multiple board, and had actually 3,500 subscribers. He asked if there was a board in London as large as that.

The WITNESS said that the board at Lime-street was constructed either for 5,000 or 6,000 subscribers. The multiple board was divided into sections, each section providing for 200 subscribers, so that a multiple board for 10,000 subscribers could be provided by dividing it into 50 sections. It would require four additional operators for each 200 subscribers, and the cost would be *pro rata* with the greater number of subscribers. Additional operators would be required for working the junction lines, and as they would have to provide for early and late duty, for sickness and for holidays, the extra cost would not be limited to the mere wages of the four operators.

Replying to Mr. Moulton as to the position of the public under the Agreement, in the event of the service of the Company being inefficient, and there being no penalty on the Company or restriction as to rates, the WITNESS said it could be met by the Post Office opening a competing exchange. Therefore competition was not impracticable, but it should not be engaged in by municipalities. If it was only one town which they had to consider then the Postmaster-General would not have much difficulty in inducing the Treasury to give its consent, even if it involved a loss.

Mr. MOULTON: That is the kindest word I have heard for the Treasury for a long time.

The CHAIRMAN: Especially if the town gave a guarantee.

The WITNESS: Just so.

Mr. R. E. CROMPTON, President of the Institute of Electrical Engineers, speaking for that body, said that their general views were that the effect of the monopoly which had existed up to the present time had been to entirely deaden the interest which the members of the Institute had taken in telephony, so that out of the total membership of over 2,000 there were only 45 who devoted themselves to telephony, 31 of whom were in the employ of the National Telephone Company, 10 held situations out of England, and there were only four in England who were independent.

The CHAIRMAN: I think without exception every witness has advocated taking over the system by the State; would not that have a more deadening influence?

The WITNESS said it was possible that it might have; but it could not be worse than at present. From the point of view of spreading and encouraging a knowledge of telephony over a larger number of persons than at present, he would oppose the State taking over the system, though from the point of view of convenience to the community it would, no doubt, have great advantages. He thought the balance of advantage would be in the State taking it over after more information and knowledge of the subject had been gained. By adopting a system of competition, a great stimulus would be given to invention, and great improvements would be introduced which do not exist at present. The progress of the telephone would be analogous to that of the electric light, which had made such great strides in consequence of its being free and open.

The CHAIRMAN: Do you think the telegraph service has become crystallised instead of having been in a state of improvement?

The WITNESS said that he considered telephony was very different to the telegraph. We were only on the way to finding out what was to be done in the way of transmitted speech. Probably the thing they were most looking forward to was telephony without wires, and that was a thing in which invention was discouraged by the present state of things. Asked if he suggested that his views were the views of the whole body and of Lord Kelvin in particular, the WITNESS said he did not know what Lord Kelvin's views were, but the views he had expressed were the views of the Committee and a great number of members with whom he had conversed. Professor Hughes, the inventor of the microphone and the transmitter, was strongly in favour of competition from the point of view of the development of the system.

The CHAIRMAN: Of course you are aware that the telephone in England has gone through a period of unlimited competition which has resulted, from causes which we need not go into, in the abolition of all competition and the amalgamation into one system?

The WITNESS replied that the patent lasted for twenty years, and that as long as that lasted there was really no competition. With competition in the electric light, the result had been lower prices and great improvement in the quality of the article. The telephone must be divided into two heads, the trunk lines and local lines, and he thought we in England especially wanted a development of the telephone without the trunk lines. Where we compared so unfavourably with other countries was the absolute want of telephony among the poorer classes in the villages and towns, as it was found in Sweden. He did not think there would be any real difficulty, from an engineering point of view, by having two competing systems in the same area, half the subscribers being on one system and half on the other; but in that matter he did not speak as an expert. What he was really speaking to was this: he was an educator of young men for the electrical profession, and he had had a large number of pupils, but the electric light and the transmission of power filled their thoughts, while telephony was a subject on which they did not wish to learn, and which they did not know. Electric light and electric power schemes were carried out by those young men going down into the country, starting local affairs, and getting local capital. He believed the same thing would be done with telephony by young men on the country-side getting small exchanges and fostering them all over the country.

The CHAIRMAN: So you advocate young men starting telephone systems throughout the country wherever there is sufficient capital?

The WITNESS said he did, and he thought there would be a great increase in that way. They would have nothing to do with the trunk lines, but would simply be small exchanges for local purposes.

Lord STANLEY asked what chance those young men would have starting in a small district against a powerful telephone company.

The WITNESS said it would not be against them, but would be filling a want that was not already filled. An exchange could be commenced with 20 or 30 subscribers very cheaply, and with very small capital, and the wayleaves could be arranged through the parish or district council.

Lord STANLEY: Have you any reason to suppose at the present moment the National Telephone Company would be indisposed to grant such an exchange where there was a sufficient number of subscribers to make it worth its while?

The WITNESS said that the reason was that £10 was too high, and that those young men starting an exchange on their own account would be able to do it cheaper than the National Telephone Company, or that at any rate we could do it as cheaply as was done in foreign countries. If such exchanges were then—if the demand justified it—on passing an examination by the Post Office and certified as being fit to be admitted to the trunk lines, they should have access to the trunk lines just the same as the National Telephone Company.

Replying to Mr. Snape, who pointed out that since the Government had taken over the telegraphs far greater progress had resulted than previously, the WITNESS urged that before the acquisition there was competition, and Prof. Hughes had declared that if there had not been that competition his type-printing telegraph would never have been taken up. Some of the members seemed to think that the telephone had got to a position

Digitized by Google

at which much further improvement was not possible, and that also tended to deaden the interest in the subject, while naturally the Post Office servants did not say much about what was going on, and there were not so many discussions on matters of detail connected with telephony as there were on other electrical matters which were burning questions of the day. It was not the opinion of the members that the progress in the telegraph had been more rapid than it was before. If the choice remained between the State taking over the telephone or continuing the present arrangement with the National Telephone Company, he would prefer the former. He looked upon limited competition as a means of spreading telephony all over the country. He saw telephony spreading very slowly at present, partly on account of the high prices. He thought competition would lower the prices and educate the public in the use of the telephones, for users were not educated in other countries. He attributed that backward state to its being in the hands alone of the National Telephone Company and Post Office.

Prof. SILVANUS THOMPSON gave evidence in support of the view urged by Mr. Crompton, stating that he had acted as adviser to various companies in telephonic matters since 1881. He wished to emphasise the view derived from conversation with other members of the Institution, that there was a general feeling that there ought to be no monopoly in the telephone business, unless it was a monopoly for which the holders should be responsible to the public through Parliament; in other words, that unless the system were taken over by the State they regarded monopoly as a thing to be deplored.

The CHAIRMAN asked the witness whether he urged that view in the interests of the telephone users, or in the interests of the profession, as tending to open up a career for a larger number of students.

The WITNESS said he certainly urged it in the interests of the public, because a monopoly could not be good for the public. Competition, he thought, would bring about a more effective service to the public.

The CHAIRMAN: Admitting that the Company had a license for 17 years, you think there should be competition until the close of that license, and that then the State should take it over?

The WITNESS: Yes. He also wished to emphasize Mr. Crompton's view in relation to the effect that it had upon the training of young men. He had had to do with the training of young men for the last 10 or 12 years, and had had something like 4,000 young men who had attended his classes, but very few had come to be educated in telephony. It had been forced upon him that the education of the young telephonic engineer was not being conducted in this country upon really scientific grounds; that was to say, there did not appear to be much encouragement in that branch of the profession. Parents came to him about placing their sons, asking whether they should send them to such and such a firm, or put them to college for a couple of years with a view to their careers, but very seldom did it occur to them to ask whether telephony offered a career for young men. He sometimes suggested it, but the suggestion was seldom accepted. They enquired about careers as patent agents, submarine telegraph engineers, electric lighting, but the particular branch of telephony was very seldom asked about.

The CHAIRMAN: Then you suggest that the future policy should be adapted to opening careers for these young men.

The WITNESS said he considered that it was not an unimportant matter to bear in mind in framing the future policy; another thing which had tended to deaden interest in telephony was the enforcement of the patent, which had prevented anybody else doing anything in this country whatever, and had had a bad effect upon its progress and development.

In reply to Mr. Snape, the WITNESS said that he considered it would be quite as economical to take over the appliances of the Telephone Company now as at the end of the 17 years.

Replying to Lord Stanley as to the young men starting new exchanges being able to stand against the competition of a large company, the WITNESS said he thought they would have a good chance of success if they were acting as agents of the local authority; he would not prevent private enterprise but would prefer to have the local bodies as a backbone. Steps would have to be taken to prevent the National Telephone Company first cutting out the small exchanges by low prices, and then raising the price after they had swamped their competitors.

Replying to Mr. Tully as to the Plymouth case, he said he could not understand how the Post Office could give a licence to allow the licencee to interfere with their own business there. It seemed to him to be monstrous.

Mr. TULLY: There are many things we cannot understand.

In reply to Mr. Moulton, the WITNESS stated that he acted as the adviser of the London and Globe Company, which had litigation with regard to the patent. The idea of that Company was to have various exchanges for various trades—one exchange for tea-dealers and another for lawyers; but they would be able to have inter-communication between the several exchanges, so that the lawyer could communicate with the tea merchant, and *vice versa*. He agreed with the suggestion that municipalities might be expected to be the most efficient providers of a competitive local system. The question of inter-communication between competing systems would depend upon the terms upon which they held their licences: but he thought that such means ought to be arranged for.

The Committee then adjourned until Friday.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April 26, 1895.*

Newspaper Amalgamation.—The publishers of the *Electrical World* have purchased the *Street Railway Gazette*, which will hereafter be issued from the office of the former publication. The *Gazette* was founded in 1886 as a monthly, and changed to a weekly in 1892, being the only weekly publication in the United States devoted entirely to street railway interests.

The Metropolitan Elevated Street Railway of Chicago.—The first extensive electrically-operated elevated street railway in the United States was formally opened last week. This railway, which is 13½ miles in length, is built on private right of way, the expenditure for land and construction amounting to $12,000,000. There are two motors to each motor car, hauling from four to six trailers. The speed of express trains is to be over 30 miles per hour. The motor cars resemble the passenger cars in external appearance. At each end there is a compartment one-half the width of the car for the motorman, the remainder of the car being used as a smoker. The present generating equipment consists of four units, two of 1,000 H.P. and two of 2,000 H.P. The dynamos are similar to those used on the Intramural road at Chicago. Each motor is equipped with a sliding shoe on either side; only one of these is ordinarily used, but in passing cross-overs the shoe employed on the return trip on the other track is temporarily in use, being thrown in automatically.

The Westinghouse and General Electric Companies.—The negotiations between the General Electric and the Westinghouse Companies in regard to an agreement as to the common use of patents have been suspended, at the instance of the executive officers, it is generally believed. Mr. George Westinghouse, it is known, was opposed to the proposed arrangement, which was suggested by those representing the financial interest of the two companies. The general opinion is, that the difficulty which brought the negotiations to a standstill probably occurred when the valuation of the Tesla patents came under consideration.

CORRESPONDENCE.

EARTHING THE MIDDLE WIRE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The subject of the leading article in your issue of April 26th is one worthy of discussion, and one that will probably receive much attention in the near future.

In their report (given in your paper of the above date) to the Municipality of Altenburg on the question of a bare middle conductor in a three-wire distribution system, Messrs. Slaby and Gisbert Kapp dwell on the difference of potential which will exist between several points of the earthed middle conductor when a considerable current is flowing in the cable, and the consequent electrolytic action and disturbance of telegraphs and telephones by wandering currents between the different points. The report leads one to suppose that the middle cable will be earthed throughout from the central station to all parts of the district, with a considerable loss in the conductor when the current in the two outer cables is not balanced.

The most sensible means of overcoming this difficulty is by protecting with slight insulation the middle conductor of the several sets of feeders issuing from the central station, and also the middle conductor of the distributing network; let the middle conductor be earthed, not at the generating station, but only at the points where the feeders are connected to it, and whence pilot wires are carried back to the station, and at which points the difference of potential between the middle and outside cables is, or should be, always kept similar and constant. Thus, there being no difference of potential between these

Digitized by Google

earthed feeding points, the injury from electrolytic action, or disturbance to telegraphs and telephones, will not occur.

The authors of the report enlarged on the benefit of an earthed middle conductor for discovering leaks on the outer cable, and the automatic discovery of weak spots by the fusing of cut-outs. In your article you question whether fuses will act so obligingly for the tracing of leaks, and you admit that on both the outer mains—positive and negative—leakage will still occur. Concentric cables, with the outer conductor earthed at the points as suggested above, together with concentric wiring in buildings, will remedy this evil. With this arrangement the positive and negative conductors, hitherto called the outside cables, are now each enclosed in an outer sheathing of stranded wires and well insulated from it. The sheathing of each cable forms the "middle or neutral conductor"; is slightly insulated, and earthed at the feeding points. The sheathing of each cable is connected at frequent intervals. As the positive and negative conductors are enclosed within the "middle or neutral conductor" from the generating station right through to the lamps, the possibility of leakage to earth does not occur.

There are other benefits which I cannot introduce into this letter, owing to its length already, but they all point to the probability of this method of cable laying and wiring being one that will be largely used in the future.—Yours, &c.,

SIDNEY SHARP.

34, Victoria-street, S.W., May 8, 1895.

SLIDING SCALE CHARGING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to charging for electric lighting on a sliding scale, I think I can claim priority in this. In 1882 I had charge of one of the pioneer stations of the Metropolitan Brush Company, in High Holborn.

Some of the customers complained at paying the same annual rental for their arc lamps while closing at 8 p.m., as the public-houses, hotels, music halls, &c., who had the light till 12:30 a.m. I pointed out that the plant (which was about 100 per cent. higher then than now) had to be provided for them whether they used it or not. To meet them, I took the first cost of the plant, added a percentage for management, and divided it by the lamp output (arc lamps). From this I got a fixed sum per lamp, and in addition charged so much per hour for the time they burned the light. I had some difficulty in persuading the Company to adopt my suggestion, but succeeded in a few instances where the people refused to accept any other terms. I have always maintained that a sliding scale charge was the only one that would meet our requirements, and for years was ridiculed for thinking that any but the orthodox pattern, such as the gas or water meter, would be accepted.

It is now an accomplished fact. As regards the systems, Mr. Wright rather under-estimates the value of the long-hour customer, while Mr. Ward Leonard's example of the generator and fan is over-stated. I think it possible (while fully admitting the beauty of Mr. Wright's apparatus) without such apparatus to hit a fair mean.

The electric light is the poor man's light; that is, the lower and middle class. Their consumption is steady and regular, they are rarely away from home, and use their full requirements from 1,600 to 1,700 hours per year. Had stations started with dense residential neighbourhoods, instead of shops, electric lighting stations would have doubled their progress by now.—Yours, &c.,

ERNEST G. PINK.

Electricity Works, Ayr, May 7, 1895.

CURIOUS VACUUM TUBE PHENOMENA.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I should be glad if any of your readers could furnish me with an explanation of the undermentioned effect, to which I have been unable to find any reference in either text-books or in researches on kindred subjects. After a vacuum tube had been caused to glow by means of a Wimshurst machine, it was observed that on stopping the machine, and removing the tube to a distance of several feet, or in fact taking it out of the room altogether, the tube still continued to glow for a space of a minute or two. In some cases the tube appeared dead, but on placing the hand directly round the centre bulb, a sudden glow shot through the tube, and by changing the hand round so as to encircle a further part of the bulb, yet a second and third glowing discharge occurred. Also, if one extremity of the tube be connected to one terminal of the machine, while the tube is held in the hand, the usual brush-like glow occurs, but terminates at the hand. If, after stopping the machine and removing the tube, the other hand is allowed to touch either extremity, a sharp shock is felt. The whole of these effects are exceedingly beautiful when seen in a perfectly dark room. Often the waves of light go surging instantaneously from both ends of the tube to its centre. On several occasions I have noticed a small cloudy film of light swirling round the inside of the centre bulb of the tube, accompanied by a feeble but distinct crackling sound. The tube can also be held to the prime conductor of the machine in such a manner that a discharge (like that of a Leyden jar) takes place at regular intervals between one extremity and that outside portion of it which is in contact with the machine.

The cause of the phenomenon appears to be that the glass of the tube in some way acts as a dielectric, but I should be glad if someone would furnish a complete explanation.—Yours, &c.,

W. LOMAS.

LEGAL INTELLIGENCE.

Elton v. St. Pancras Vestry.

On Wednesday, in the Bloomsbury County Court, London, W.C., this case came before Judge Bacon. It was a claim for £40 for damage to a wall and lamp outside the premises of the plaintiff by an explosion which occurred in the electric mains belonging to the defendants in December last.

Mr. Elton, the plaintiff, said the wall was an old one, and was bulged before the explosion. When he went there he had it pointed with cement, but he thought it would have lasted 10 to 14 years longer but for the explosion. Inside the wall the earth was higher than the footpath on the outside, and that would have a tendency to bulge it. Water would run away from the wall in consequence of the fall of the ground. The Vestry shored the wall up when they excavated to lay the mains.

Witnesses were called who proved that the cracks were due to shock, and that the wall was now dangerous. The wall was probably 40 years old.

For the defence it was admitted that something was due to plaintiff, and any bona-fide claim would be paid and the Vestry would square affairs after with the Gas Company. They had paid 10s. into Court which they were of opinion was ample to cover the damage to the lamp. As to the wall, the Vestry alleged that the damage was due to the pressure of earth, old age and other causes, but there was absolutely no damage done to it by the explosion.

Evidence to this effect was called, and his Honour reserved his judgment, as he was desirous of seeing the wall.

On Thursday he gave judgment, and said there being no dispute about the lamp, and it being proved that 43s. was paid for repairing it, plaintiff would recover that amount with costs thereon. In his opinion the wall was dilapidated, and the explosion did not damage it. He thought the wall had sunk in consequence of the sinking of the subsoil.

Judgment for the plaintiff for £2 3s. and costs thereon.

Planet Electrical Engineering Company (Limited) v. Railway Clearing House Committee.

This case came before Mr. Justice Mills and Mr. Justice Charles in the Queen's Bench on Saturday last, in the form of a special case on certain findings of Mr. J. Fletcher Moulton, Q.C., M.P., in his award in an arbitration between the plaintiffs and defendants. The plaintiffs, under agreement with defendants, undertook to do certain work in putting up an electrical installation in the defendants' offices at King's Cross. After the plaintiffs had carried out the work, disputes arose as to the sum which they were entitled to be paid, and the matter was referred to arbitration in accordance with a clause in the specification. After the plaintiffs had completed the work, the contract sum, together with the agreed price of certain extras, for which orders in writing were given by the defendants, were paid to the plaintiffs; but the plaintiffs claimed to be paid further sums for certain departures from the work of the specification directed by the consulting engineer to the defendants, to whose satisfaction the whole of the work was to be done. The provisions of the specification as to extra or altered work and to the settlement of disputes was as follows:—

> "Any extra work or any deviation from the work, as laid down in this specification and the schedules attached thereto, is to be entirely subject to the direction of the consulting engineer to the committee. Extras will not be allowed for unless an order is obtained from the consulting engineer to the committee in writing, specifying the nature of the work and his approval thereof, together with the cost which may attend the same."

Digitized by Google

The arbitrator found (*a*)—That there were no extra works required by the engineer or executed by the plaintiffs (other than those under written orders which had been paid for), with the exception of nine distributing switchboards, which he found not to have been included in the tender of the plaintiffs or estimated for in their price, but which were included in the specification, and were required to be executed by the engineer on that ground.

(*b*) That there were departures from the work of the specification directed by the engineer, and carried out by the plaintiffs, consisting mainly in requisitions by the engineer that the work described in the specification should be carried out in an unusual and more costly manner, not within a true or a reasonable interpretation of the specification and not implied thereby, but which the engineer insisted upon as being within the same. He (the learned arbitrator) found that this opinion of the engineer was erroneous.

(*c*) That the engineer required the contractors to do work in the nature of cutting away and making good which was under the contract to be done by the architect to the committee and not by the plaintiffs, and that he did so by reason of his erroneously interpreting the terms of the contract in that respect.

The questions for the Court therefore were whether the plaintiffs were entitled to be paid for any or all of the work referred to in these three heads, and their Lordships, after hearing arguments by Mr. Roger Wallace for the plaintiffs, and Mr. Montague Lush for the defendants, gave judgment for the plaintiffs on all the deviations, with costs.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NOW READY.

SPECIAL NOTICE—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Although about 100 pages are added to the book, no addition is made to the price, which is 7s. 6d., post free 8s. 3d., abroad 9s.

"THE ELECTRICIAN."—A special notice concerning certain changes in the price, &c., of this journal will be found on page 52.

TENDERS INVITED.—The Corporation of Birkenhead invite tenders for the supply and erection of apparatus and plant for their electric supply works. Some further particulars will be found in our advertisement columns. The requirements include boilers, engines, dynamos, a battery of storage cells, instruments, cables, street boxes, &c. Plans will be ready after the 8th inst., and all further information can be obtained at the office of Mr. Alfred Gill, town clerk, Town Hall, Birkenhead; or at the office of Mr. J. N. Shoolbred, C.E., 47, Victoria-street, London, S.W. The contract is in five sections, which can be tendered for separately. Tenders must be in by 12 noon of the 23rd inst.

——— The Directors of the Great Eastern Railway Company invite tenders for telegraph materials, bolts, screws, rivets, cast-iron pipes, tools, &c. Tenders to be in by the 16th inst.

TENDERS ACCEPTED.—The Worcester Board of Guardians have accepted the tender of Mr. J. F. Santonna for the supply of fittings for the installation of the electric light in a portion of the workhouse.

——— The Brighton Town Council at their last meeting accepted the tender of Messrs. A. W. Field and Co. for the extension of the electricity station.

——— The St. Pancras Vestry have accepted the tender of of Mr. J. Steed, of Chalk Farm-road, N.W., for building the sub-station in St. Andrew's-gardens, for £415. 8s. 5d.

——— The Gas and Electricity Committee of the Bolton Corporation have accepted the tender of Messrs. S. Z. de Ferranti and Co. (Limited) for the supply of an alternator for their electricity works.

SALE BY AUCTION.—Messrs. Wheatley Kirk, Price and Goulty will sell by auction at the works of the Leeds Machinery Stores Company, Kirkstall-road, Leeds, on Tuesday and Wednesday, the 21st and 22nd instant, the entire stock of new and second-hand machinery detailed in our advertisement columns. Particular attention is called by the auctioneers to the large number of valuable machines to be disposed of. Further particulars and catalogues can be obtained at the stores, Kirkstall-road, Leeds, or of the auctioneers, 49, Queen Victoria-street, London, E.C., and Albert-chambers, Albert-square, Manchester.

DISSOLUTIONS OF PARTNERSHIP.—The partnership heretofore subsisting between A. G. Pope, G. M. Body, and C. F. Barker, electrical and sanitary engineers, trading under the style of Pope, Body and Co., of 26, Pall-mall, Liverpool, was dissolved by mutual consent on the 7th inst.

——— The partnership hitherto existing between G. H. Hardman, H. C. Ashworth, and C. H. Lomax, under the style of H. Ashworth and Co., electrical and heating engineers, 8, Fleet-street, Bury, has been dissolved. Debts by H. C. Ashworth and C. H. Lomax, who continue the business.

APPOINTMENTS VACANT.—The Governors of the Woolwich Polytechnic invite applications for the following appointments:—(1) Principal of the Polytechnic, (2) Head of Social and Recreative Department, (3) Clerk to the Governors. Some particulars are given in our advertisement columns, and all further information can be obtained with forms of application from the office of Mr. W. Garnett, the hon. secretary, 13, Spring-gardens, S.W. Applications have to be in by 10 a.m. of May 25th.

——— The Governors of the Wandsworth Technical Institute are prepared to receive applications for the post of Principal of the Institute. The salary commences at £350. Particulars can be obtained from the Hon. Secretary, 4, Galveston-road, Putney, London, S.W., and applications must be in by the 15th instant.

APPOINTMENT.—At the last meeting of the Commission of Sewers, Mr. A. A. Voysey, the electrical inspector, was appointed consulting electrician to the Corporation.

BUSINESS CHANGES.—Owing to a large increase in their business and the intention to extend the firm's field of manufacture, the Nalder and Harrison Construction Syndicate (Limited) have purchased the lease of extensive premises at Bow Common-lane, London, E., known as the "Invicta" Works, together with the complete and efficient engineering plant and machinery situated therein. By this arrangement the firm will be enabled to carry out work of the very largest and heaviest description in addition to their present extensive output of electrical measuring and testing instruments, switchboards, &c. The Syndicate intends to produce as soon as possible standard types of dynamos, motors, transformers, steam engines, &c. As the work of transferring the existing plant at Trafalgar House, and completing the new arrangements is of considerable magnitude, the works at Trafalgar House will be kept open until the new works are as nearly as possible complete. Due notice of the final removal will be given, and in the meantime it is requested that all communications be addressed to the head offices at 47, Victoria-street, London, S.W.

LIQUIDATIONS.—Notice is given that the creditors of the Akester Electric Syndicate (Limited) must send in their names and addresses, with particulars of their debts or claims to the liquidator, Mr. J. Durie Pattullo, 30 and 31, St. Swithin's-lane, London, E.C., by June 10th next.

——— A meeting is to be held at 41, Piccadilly, Bradford, on June 10th next, at 2 p.m., for the purpose of receiving an account of the winding-up of the Crossley Telephone Company (Limited).

BANKRUPTCIES.—A receiving order has been made against Philip Crosby Pope, electrical engineer, of 6, Castle-street, Hapton, near Burnley.

——— In the failure of D. and G. Graham, of Douglas-street, Glasgow, a meeting of creditors is to be held on the 16th inst., at 12 o'clock at the Religious Institution Rooms, 200, Buchanan-street, Glasgow.

ALLGEMEINE ELECTRICITÄTS-GESELLSCHAFT, BERLIN.—We have received from this firm the English edition of a brochure on tramway traction, giving full information on the subject, with illustrations and diagrams of lines equipped by the Company. Twelve of these lines are already in operation and thirteen are in course of erection, with a total length of 372 kilometres (about 225 miles), and 627 motor cars. The most noticeable are the lines at Halle, Breslau, Essen, Chemnitz, Christiania, Dortmund and Lübeck. In all cases the overhead trolley system is employed. The working pressure is 500 volts. The album is nicely got up, and the illustrations are very good.

AWARD.—Messrs. Crompton and Co. have received the gold medal and diploma for their exhibits of cooking and heating apparatus at the Universal Food and Cookery Exhibition, held this week at Portman Rooms, London, W. This is the highest award possible, and makes 5 diplomas and 4 gold medals awarded to the firm during the past two years.

MACHINERY USERS' ASSOCIATION.—The annual report of the Committee of this Association to March 31st is issued, in which reference is made to the steps taken to bring the objects of the Association before machinery users. The Bill for exempting tenants' machinery and tools from rating, which was read a second time by a considerable majority in 1894, has again passed its second reading in the present Session, and now only awaits third reading, which has been put down for June 19th. The Committee ask for the continued support of all interested in the movement.

Digitized by Google

Cooking and Heating Apparatus.—Messrs. Crompton and Co. are keeping fully abreast of the demand for apparatus required for cooking and heating by electricity, and in their latest price list show several additional items recently completed. The illustrations include a neat-looking breakfast cooker with hot plate and oven, several ornamental electric urns, a bronchitis kettle on stand, hot cupboard, &c. Accompanying the list are some useful hints on the use of the apparatus. The same firm are also issuing a pamphlet containing a lecture by Mr. H. J. Dowsing, entitled "Cooking by Electricity," of which copies can be obtained, price 2d.

Electric Machinery for Battleships.—The new battleship "Renown," which was launched from Pembroke Dockyard on Wednesday, has been so fitted as to provide for the guns on board to be operated entirely by hand (which is unusual in large vessels), by steam power, or by the aid of electric motors. In the case of the battleship "Barfleur," for one of the mounts electric motors were fitted with the view of testing their power for working the guns, and the results are stated to have proved eminently satisfactory. It is, we learn, in contemplation to fit electrical mechanism to the other mount on the same ship, and also on the "Centurion." The whole of the machinery for the "Renown" has been constructed by Messrs. Maudslay, Son and Field, of London, S.W., including the electric motors.

Automatic Injectors.—Messrs. Green and Boulding, of Featherstone-street, City-road, E.C., send us a copy of their latest price list of the "Buffalo" automatic injector, for which the makers claim that it is an efficient and economical boiler feeder, being operated entirely by a single lever under all conditions, whether lifting its supply water up to 12ft. or receiving it under pressure from overhead or from a main supply, no regulating valve or other regulation being needed. The B class injector, it is stated, is specially suitable for stationary boilers and can be graded for 50 per cent.

Electro-Medical Instruments.—Messrs. A. Hurst and Co. have just issued a catalogue of electro-medical apparatus manufactured by them, in which is illustrated and described a large variety of instruments, including batteries, induction coils, sledge coils, handles, electrodes, controlling and measuring instruments, and other accessories, the prices for all of which are given.

"The Engineering Magazine."—The May issue of this magazine fully maintains its usual high standard of excellence both as regards matter and illustrations. Its contents include:—"Meaning of the Recent U. S. Patent Decision"; "The Proposal to License Architects"; "How Holland was Made"; "The Educational Influence of Machinery"; "The Great Steamers of Long Island Sound"; "Practical Hints for City Officials"; "Economy in Railway Operation"; "A Marvel of Mechanical Achievement"; "The Modern Science of Electric Heating"; "Mine Reports and Mine Salting," and the increasingly useful Review of the Industrial Press. The new number, and nearly all back issues, may be obtained at the office of the European Edition, 1, 2, and 3, Salisbury-court, Fleet-street, London, E.C.

"Shipping."—This is the title of an enterprising contemporary issued monthly, and which enters on its second year's existence with the issue for May, 1895. *Shipping* is well printed on good paper, and contains a mass of very interesting matter, and those interested in things nautical will appreciate a fully-illustrated description of the "Scott," the famous South African liner. Other fully-illustrated articles include "The Coaling Stations of the World" and "A Visit to the Engineering Works of Messrs. J. and C. Hall (Limited) at Dartford."

"Daily Tenders and Contracts."—No. 1 of a new daily journal, under the above heading, was published on Tuesday last. The paper is started with the object of keeping business men in touch with the requirements of Government departments, the local authorities, railway and shipping companies, and other large trading concerns throughout the world. That there is ample room for such a journal there can be no doubt, and when once the staff get fairly into work a very useful publication will be added to the large number of periodicals now seeking public support. The publishing offices are Temple-chambers, London, E.C. The price of the paper is 2d.

Aberystwyth.—The Town Council at its next meeting will consider a recommendation of the Public Works Committee that £900 be borrowed for electric lamp pillars out of a total of £13,000 for which application for borrowing powers is to be made to the Local Government Board.

Artistic Electric Lighting.—The *Art Amateur* for May contains an interesting article on "Designs for Electric Lighting for the House."

A New Electrolytic Process.—On Saturday last the officials of the General Electrolytic Company explained to a gathering of persons interested in their new process for obtaining alkali the particulars of the process at their experimental works at Farnworth. The apparatus has been very much simplified, and there is now no alkali waste to dispose of.

Aberdeen.—At Tuesday's meeting of the Corporation a report from the Sub-Committee specially appointed to consider the question of the supply of electric motors was discussed. The report contained a proposal that the charge for current for motive power should be fixed at 4d. per unit for day supply. The report was adopted. The following list, showing the price per unit charged for lighting and power purposes by a number of Local Authorities and supply companies, accompanied the Sub-Committee's report:—

Local Authorities.

	For lighting.	For power.		For lighting.	For power.
Brighton	7d.	4d.	Coventry	6d.	4d.
Bristol	6d.	4d.	Blackburn	7d.	5d.
Belfast	7d.	4d.	Bolton	8d.	5½d.
Manchester	8d.	sliding scale to 2¾d.	Bradford	5d.	3½d.
			Lancaster	7d.	4½d.
			Leeds	6d.	3d.
Hull	6½d.	5d.	Nelson	5d.	4d.
Halifax	6d.	4d.	St. Pancras Vestry	6d.	3d.
Sunderland	6d.	3½d.			

Supply Companies.

	For lighting.	For power.		For lighting.	For power.
Hove	8d.	6d.	Norwich	8d.	4d.
Newport	6d.	4d.	Scarboro'	6½d.	5¾d.
Cheltenham	6d.	3½d.	Southampton	8d.	6d.
Derby	6d.	3d.	Thetford	7d.	6d.
Galway	6d.	3d.			

Bangor.—The Town Council, at their meeting on Wednesday, decided to appoint an Electric Lighting Committee.

Bolton.—The Board of Guardians have appointed a sub-committee to obtain the necessary tenders for lighting the Board's offices, &c., by electricity.

Bootle.—At the meeting of the Town Council on Wednesday, the Electric Lighting (Special) Committee was dissolved, and the work of lighting by electricity of the Town Hall and municipal buildings placed under the control of the Parks and Baths Committee. Information has been received that the Board of Trade have decided to grant the Provisional Order applied for by the Corporation.

Cable Schemes.—The Under-Secretary for the Colonies, in reply to questions in the House of Commons, said that her Majesty's Government had not received any request from or through the Government of Canada to call a conference of the Colonies interested with a view to arranging the details of the laying and maintaining a cable across the Pacific Ocean between Canada and Australasia. The Postmaster-General also stated that about four years ago a request was made that a telegraph cable should be laid to the Island of Sark, but as the estimate of revenue fell far short of the estimate of expenditure, the Treasury did not see their way to sanction the extension.

Chiswick (London, W.).—The contractors for the electric lighting of this district expect to have the mains completed by August next.

Coventry.—It is now a couple of years since the steam trams ceased running, and definite arrangements have been completed for the equipment of a service of electric tramways by the overhead system between Coventry and Bedworth. Mr. Charles Haywood, the local contractor, has commenced operations at the depot, Foleshill, for the requisite buildings.

Dowlais.—The agitation against the exorbitant charge for gas made by the local gas company has culminated in a demand for the electric light. The president of the Chamber of Trade at a recent meeting complained of the unfair treatment to which tradesmen were subjected by the gas company, and called attention to the fact that the Dowlais Iron Company were about to supply all their officials with the electric light, and he hoped they would be able to induce the Company to extend the installation to the town.

Ealing.—An accident having occurred to one of the transformer stations in consequence of some work which was being carried out by the Grand Junction Waterworks Company, the clerk to the District Council informed the Company that it would be held responsible for the damage caused. The Company's engineer, in reply, wishes to know "how the Company and the Council stand in regard to this new invention."

Edinburgh.—Prof. Kennedy has advised the Electric Lighting Committee of the Town Council that the use of change-over switches is dangerous, may cause accidents, and should not be sanctioned. On this subject a notice of motion has been given, "That it be remitted to the Lord Provost's Committee to consider the advisability of granting the use and privilege of the city electric light to those parties who possess and use private electric plant, and to report."

Digitized by Google

ELECTRIC LIGHTING IN FRANCE.—La Société Normande d'Electricité has just given out a contract for four Willans triple-expansion engines, each of 180 H.P., for use at the electric supply station at Rouen. The engines will be connected to four Alioth dynamos.

FAIRFIELD (BUXTON).—The Urban District Council at their last meeting decided to appoint an electric lighting committee to report to the Council on electrical matters generally.

FULHAM (LONDON, S.W.).—At the last meeting of the Lighting Committee of the Vestry a Sub-Committee was appointed to consider and report upon (1) the desirability or otherwise of lighting the Town Hall with electric light; (2) the existing facilities in the hall for providing such electric light by means of duplicate gas engines, dynamos, and, if possible, accumulators; and (3) the probable cost of such provision and also of wiring, switching, incandescent lamps, and all extra wages for skilled supervision or attendance. Mr. Cranfield said it would be a great improvement if they had the electric light installed, and would save the decorations of the Town Hall.

GALATZ (ROUMANIA).—A concession has just been granted to a French company for the construction and operation during a period of 38 years of a line of electric tramway in this town on the accumulator system.

HAMPSTEAD.—The large number of applicants for the post of Chief Electrical Engineer to the Vestry have been examined by the Electric Lighting Committee, and the following six names have been left, from which the final selection will be made:—C. H. Cottam (Hanley), G. B. Dunn (Sardinia-street Station, Metropolitan Electric Supply Company), E. Sayer (Hampstead Vestry Supply Station), A. M. Sillar (chief engineer to Messrs. J. G. Statter and Co.), J. E. Stewart (Derby), and H. D. Munro (Exeter Electric Lighting Company).

HANLEY.—Mr. R. Walton, C.E., Local Government Board inspector, recently held an inquiry into an application by the Corporation for sanction to borrow a further £5,000 for electric lighting extension in the borough. The town clerk (Mr. A Challinor) stated that the Corporation had authorised an application for sanction to raise a further loan of £20,000 for extending the electric lighting mains and appliances, and he asked the inspector if the matter could be taken into consideration now. Mr. Walton said that he was limited to the terms of the notice, but the subject might be mentioned incidentally. Mr. Challinor explained the details of the extensions for which the present loan of £5,000 was required, and the borough surveyor and electrical engineer also gave evidence. The Mayor said the Council were unanimous in this application, and they were supported by the town. The applications from customers were so numerous that there were already 2,000 lamps applied for which they were unable to supply, and during the coming winter applications would much increase this number.

IPSWICH.—In reference to the decision come to by the Town Council to apply for an Electric Lighting Order, the Electric Lighting Committee report that they have consulted Prof. Kennedy on the subject of a suitable site for an electricity supply station and the cost of the necessary works and plant, but, in view of the large expenditure involved, recommends that no further steps be yet taken to obtain a Provisional Order. The discussion on the report is to be taken at the next meeting of the Council.

JOHANNESBURG (SOUTH AFRICA).—A copy of the bi-annual report of Mr. Charles Aburrow, the town engineer of Johannesburg, has been sent us. This report gives a detailed account of the work done for the period ended December 31st last, and it would appear that at Jeppe Town electricity is used for street lighting, 48-c.p. lamps being selected. Current is supplied by the Johannesburg Lighting Company, whose report for the period is to the effect that considerable additions have been made to the generating plant by the putting down of a new 60-H P. Ruston-Proctor multitubular boiler and a large Willans compound engine coupled direct to an Elwell-Parker dynamo. The report states that this was the first Willans engine of this type erected in South Africa, and that its complete success has resulted in the putting down of a number of similar engines in the locality. Four new lightning arresters have been erected, and have been tested by several severe thunderstorms and proved very effective. The suggestion that the town authorities should purchase the Lighting Company's undertaking has resulted in a proposal that the concession and works be purchased for the sum of £160,000 being approved at a public meeting of ratepayers.

KENDAL.—At the last meeting of the Urban District Council a letter was read from the Chamber of Commerce enclosing a resolution asking the Council to consider the question of supplying the town with electricity for power purposes. The Council reply that the matter is under consideration.

LANCASTER.—An interesting discussion took place at the last meeting of the Town Council on the report of the Electric Lighting Committee. Mr. Alderman Smith pointed out that unless some alteration was made in the method of charging for current, their electric lighting enterprise would never pay. It was not sufficient to make an all-round reduction, but he recommended that the charge for current should be reduced from 7d. to 6d. per unit for the first two hours' consumption, and after this time to 4d. per unit, and he announced that in this proposal he had the support, amongst others, of the surveyor and electrician. This proposal was in lieu of the recommendation of the Committee to make the price an all-round 5d. per unit. After considerable discussion the Committee's report was adopted, the amendment of Alderman Smith being negatived by 10 votes to 5.

LONDON CHAMBER OF COMMERCE.—The thirteenth annual general meeting of the Chamber will be held in the Council Room, Botolph House, Eastcheap, London, E.C., on Tuesday, the 21st inst., at 2.30 p.m. The chief business is the adoption of the report and accounts for the past year, the election of officers, and other routine matters. The annual dinner is announced to take place on Wednesday, May 29th, at the Hotel Métropole, London, W.C., at 6.30 for 7 p.m.

MANCHESTER.—At Wednesday's meeting of the City Council, in presenting the reports of the Gas Committee and the Electric Lighting Sub-Committee, Mr. Ald. Higginbottom stated that the total contribution the Committees expected to make to the City funds was between £52,000 and £53,000.

METROPOLITAN TELEPHONES.—The much enduring subscriber to the telephone has this week received more attention than is usual. The London County Council, the City Commissioners of Sewers, and the National Company have each sought his vote and interest on the question of the efficiency of the telephone service and the excess or otherwise of the subscription charge. The circular from the County Council states that the Highways Committee of that body are of opinion that the telephone service in the metropolis should be rendered cheaper and more efficient, and are anxious to know accurately what is the opinion of users of telephones in London as regards the efficiency of the present service. The subscriber is asked to give his views on the existing telephone service of the National Company, to state in what respects, if any, it is unsatisfactory, and to make what suggestions he can in the matter of improving the service generally. The circular from the Commissioners of Sewers states that evidence has been given on their behalf as to the inefficiency and costliness of the existing service of the National Company, and telephone users are invited to reply to similar questions to those set out by the County Council. Finally, the National Company asks its subscribers to say that they "do not approve of the service of the metropolis being undertaken by the London County Council, and that the service given by the National Company is reasonable, having regard to the efforts which are being made by the Company to improve it by the adoption of the twin-wire system." Very skilfully the National Company has hastened the collection of its circular, which was issued on Tuesday and collected on Wednesday. Following this, many of the unfortunate subscribers were notified yesterday (Thursday) of the imminent alteration of their telephone numbers. We strongly protest against this step being taken. It is a serious matter for business houses, many of whom are as well known by their telephone number as by their name. The most important matter of stationery has also to be considered, and if it is for the convenience of the National Company that its subscribers should be re-numbered, the least they can offer is to bear the expense of either supplying fresh stationery or some portion of its cost. In many cases this will mean a heavy outlay, and in addition the subscriber may be annoyed by finding his old number taken by a rival in trade, or that his new number has previously been owned by a subscriber with whom he wishes to have no business or other connection. Of course, the National Company will at once see that a new list of subscribers is published with the old and new telephone numbers grouped. Truly, the lot of the metropolitan telephone subscriber is not a happy one.

OLDHAM.—The Town Council have agreed to the recommendation of Prof. Kennedy referred to in our last issue, under which considerable extensions of the electric lighting scheme are to be carried out. Application is to be made to the Local Government Board for power to borrow £10,200 for these extensions. The Electric Lighting Committee are considering further applications for the supply of current from Park-road and Queen's-road.

OWENS COLLEGE (MANCHESTER).—Some particulars are given in our advertisement columns of fellowships offered by Owens College to students in arts, science and medicine.

PORTSMOUTH.—A Local Government Board inquiry was held at Portsmouth last week, and the application of the Town Council for powers to borrow a further £21,000 for the extension of their electric lighting works. There is stated to be a general outcry for an extension of the lighting area, and the Council, therefore, propose to make very considerable extensions in preference to waiting for additional applications to come in,

Digitized by Google

PRESTWICH.—At a meeting of the Urban District Council on Wednesday, Mr J. Cottrill said the lighting of the district had been improved, but a question had arisen as to whether the Council should adopt electric lighting for the whole of the township. If anything was to be done in the matter for next season it was not too early to begin. It was decided to refer the question to the General Purposes Committee.

PROVISIONAL ORDERS.—The applications made to the Board of Trade by the County of London Company and the Charing Cross and Strand Company for Provisional Orders, for the district of the St. Olave's Board of Works and the district of the Strand Board of Works respectively, have been granted. The Board of Trade has also approved the applications for Orders for the Kensington district, New Windsor and Eton, Salisbury and Southampton. Confirmatory Bills are now before Parliament.

ROCHDALE.—Some time back, Mr. Platt, the borough surveyor, was requested to prepare a report on the subject of the lighting of the Town Hall and other public buildings by electricity. This report is now published, and Mr. Platt recommends that no scheme should be hastily adopted which will not, when required, adapt itself to the general supply of electric current for public and private purposes. Owing to the fact that the probable area of supply in the town would be limited to within a radius of a mile of the sanitary works, where a considerable amount of surplus power is available, Mr. Platt recommends a low-pressure system. About 200 I.H.P. surplus steam power is available, and 100 I.H.P. can be guaranteed continuously without materially increasing the staff. Ample ground is available for the erection of buildings, and for a suitable extension if this should be ultimately found necessary. As the position of the sanitary works is not central, Mr. Platt advises that it may not be economical to use this site, especially as the cost of steam production does not form an important element in regard to the total cost of supplying electric current. The report contains several alternative schemes, estimated maintenance costs of which are given.

SANITARY CONFERENCE.—At the Conference recently held at Manchester on Sanitary Progress various questions of public interest were discussed, amongst which was the best means of lighting public schools. Dr. E. Jones read a Paper in which he strongly urged the adoption of the electric light.

ST. PANCRAS.—At their last meeting the Vestry decided to lay an electric light main from University-street along Gower-street to the parish boundary, at a cost of about £214, and at the same time the Electrical Committee were instructed to consider the question of extending the mains along Highgate-road and West Hill. At the last meeting of the London County Council, on the recommendation of the Finance Committee, it was decided to lend the St. Pancras Vestry £14,300, at £3½ per cent., for electric lighting extensions in the parish. The loan to be for a term of 42 years.

THE TELEGRAPH CLERKS.—At a conference of the Telegraph Clerks' Association in Glasgow the following resolution was carried:

"That, as the clerical and scientific duties of the Telegraph department are entirely distinct from those of the letter-sorting branch; and that as the placing of the two departments on the same level operates to the grievous disadvantage of the telegraph clerk, firstly by reducing the value of his work to that of letter-sorting; secondly by the inequitable division between the two departments of any concessions hitherto gained by the telegraph clerks; and, thirdly, the question of cost, which, when the telegraph clerk shows reason for improvements, is unduly increased by the inclusion of the letter-sorter, who has not the same grounds for consideration, we therefore claim to be treated as a separate department of the Post Office.

"TELEGRAPHY BY INDUCTION."—Mr. W. H. Preece is announced to deliver an address on this subject in the hall of the Carpenters' Company, London-wall, E.C., on Thursday, the 23rd inst., at 2:30 p.m. The chair is to be taken by Sir Albert K. Rollit, M.P., President of the London Chamber of Commerce.

TORQUAY.—The Town Council have received a report from the Electric Lighting Committee which states that many of the large ratepayers in the district proposed to be dealt with under the Council's electric lighting scheme, had intimated their willingness to take current for private lighting if it was introduced by the Corporation, but the Committee consider it will be preferable to adopt the scheme originally recommended by the Committee in August, 1893. They recommend that the refuse destructor works be dealt with separately, and not in conjunction with the electric lighting scheme, and that the necessary steps be taken for obtaining sanction to borrow £18,000 for the purpose of providing a supply station with plant and machinery under the Bath Saloons, for the lighting of the compulsory area set out in Section 17 of the Torquay Electric Lighting Order of 1891. An amendment was moved that the subject be referred back to the Committee, and that application be made to the Board of Trade for an extension of time for which provisional powers were granted, and this amendment was carried.

TOTTENHAM (MIDDLESEX).—The District Council have taken a further step in regard to the electric light by referring the consideration of the matter to the General Purposes Committee, who are to prepare a report for the consideration of the Council at an early date. With a population of nearly 100,000, it is surely time Tottenham did something to bring itself into line with the other important metropolitan districts.

TRINIDAD (PORT OF SPAIN).—The capital of Trinidad is now lighted by electricity, to the entire satisfaction of the residents. The electric light takes the place of oil lamps.

WORCESTER.—At the last meeting of the City Council it was decided to reduce the salary of the city engineer (Mr. T. Caink) from £450 to £350 a year, with annual increments of £10 until £400 is reached. This reduction is made in consequence of the appointment of an electrical engineer (Mr. E. T. Ruthven-Murray), who will relieve Mr. Caink of certain duties in connection with the installation of the electric light in the city.

WELLS.—At the recent meeting of the Town Council and Urban Sanitary Authority the electric light question was again discussed at great length, and finally the tender of Mr. A. Dixon Brown, for the public lighting of the city by electricity at £350 per annum, was accepted for three years, from June, 1896.

WEST HAM.—The Town Clerk has been instructed by the Corporation to communicate with the largest ratepayers in the district with a view of ascertaining the amount of support likely to be given to the Corporation in its proposed electric lighting undertaking.

WESTON SUPER-MARE.—At the meeting of the Urban District Council on Wednesday, a resolution was proposed "That this Council do hereby instruct their clerk to at once take the initial proceedings for a renewal or extension of the Electric Lighting Provisional Order which has been obtained for the lighting of the town by electricity." The motion was carried, there being only two dissentients.

COMPANIES' MEETINGS AND REPORTS.

Brazilian Submarine Telegraph Company (Limited).

The following is the report of the Directors of this Company for the half-year ended December 31st last, which is to be submitted to the forty-third ordinary general meeting, to be held at Winchester House, London, E.C., on Wednesday, the 15th inst., at 12 o'clock.

The revenue for the period amounted to £104,926. 0s. 7d., and the working expenses to £36,771. 18s. 2d. After providing £4,841. 6s. 8d. for debenture interest and sinking funds, and £1,490. 0s. 9d. for income tax, there remains a balance of £61,822. 15s.; to this is added the sum of £1,501. 5s. 9d. brought forward from June 30th last, making a total of £63,324. 0s. 9d. First and second interim dividends, amounting to £39,000, have been paid, and £20,000 transferred to the reserve fund, leaving the sum of £4,324. 0s. 9d. to be carried to the next account. The receipts for the half-year include the sum of £1,500 dividend to June 30th, 1894, on the Company's shares in the African Direct Telegraph Company (Limited).

The Directors with much regret have to report the death, on 3rd inst., of their esteemed colleague, Mr. Thomas Fuller, who has been Managing Director of the Company from the date of its formation.

The various sections of the Company's lines are in good working order.

NEW COMPANIES, STATUTORY RETURNS, &c.

BLACKPOOL ELECTRO-HYDROPATHIC (LIMITED).—A Company, with this title, was registered on May 6th, with a capital of £10,000, in 8,000 Ordinary shares and 2,000 £5 per cent. Preference shares of £1 each, to carry into effect an agreement between Louis Cohen, electrician, Blackpool, and Henry B. Sharples (as trustee for the Company), to acquire, by lease or otherwise, the Trevelyan Hotel, Victoria-street, Blackpool, and to carry on the business of electro-hydropathic practitioners, proprietors of electric and health appliances, baths, &c.

COUNTY OF LONDON TRAMWAYS SYNDICATE (LIMITED).—This Company was registered on May 6th, with a capital of £5,000, in £10 shares, to acquire by purchase or otherwise, and carry out contracts and concessions or other grants for making, purchasing or working railways, tramways, telegraph and telephone lines, electric and other lighting works, and for the equipment of such undertakings with electric or other plant.

MILVER PORTABLE ELECTRIC BATTERY SYNDICATE (LIMITED).—This Company was registered on May 4th, with a capital of £20,000, in £5 shares, to acquire and work certain inventions, for which provisional protection has been granted to H. Levetus, manufacturer, of Birmingham, E. M. Levetus and W. Rowbotham, electricians, of Manchester, and entitled "improvements in primary batteries" and "improvements in and relating to primary batteries," Nos. 106, 107, 231, 2,394, and 7,600; to enter into an agreement between H. Levetus, E. M. Levetus, and W. Rowbotham, and Edward A. Eaden (as representative of the Company), and to carry on

Digitized by Google

the business of electricians, electrical and mechanical engineers, suppliers of electricity for the purposes of light, heat, and motive power, and manufacturers of and dealers in electrical apparatus of every description. The subscribers, with one share each, are :—Hymen Levetus, Henry Pyton, J.P., Jacob Jacobs, J.P., Henry Headley, Frank Moss, Walter Rowbotham, and George Y. Iliffe. The first Directors are :—H. Levetus, W. Rowbotham, G. Y. Iliffe, J. Hedley, and F. O. S. Leak. H. Levetus is Managing Director, and W. Rowbotham is general manager.

T. PIERPOINT AND COMPANY (LIMITED).—This Company was registered on May 6th, with a capital of £5,000, in £1 shares, to acquire and take over the business carried on by P. T. Pierpoint, under the style of T. Pierpoint and Company, at 81, Newhall-street, Birmingham, and to carry on the business of gas and electric light fittings manufacturers, reflector manufacturers, &c.

PORT LOUIS GAS WORKS COMPANY (LIMITED).—This Company was registered on April 30th, with a capital of £35,000, in £1 shares, to acquire the gas works at Port Louis, in the Mauritius, to carry on the business of supplying gas and other light in all its branches; to construct, lay down, and fix all necessary cables, wires, lines, accumulators, lamps and works, to generate, accumulate, distribute and supply electricity, and to carry on the business of an electric lighting company, electricians, mechanical and electrical engineers, suppliers of electricity, and manufacturers of electrical apparatus and appliances.

MEXICAN GAS AND ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company to October 31, 1894, was filed on April 17th last. The whole of the nominal capital of £100,000, in £20 shares, has been taken up and issued as fully paid. Alban H. Gibbs, M.P., merchant, of 15, Bishopsgate-street Within, London, holds all but six shares.

MIDLAND ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of this Company, to April 10th, has been filed. The nominal capital is £50,000, in £10 shares. 3,139 shares have been taken up, and 3,132 of these have been issued as fully paid, the full amount having been paid on the remaining seven shares.

OGMORE VALLEY ELECTRIC LIGHT AND POWER SUPPLY COMPANY (LIMITED).—The annual return of this Company to April 3rd has been filed. The nominal capital is £10,000, in £5 shares, of which 710 have been subscribed for and allotted, and upon these the full amount has been called, resulting in the payment of £3,353, and leaving £197 in arrears.

ORME'S ELECTRIC SIGNAL SYNDICATE (LIMITED).—The annual return of this Company to January 14th has been filed. The nominal capital of the Company is £7,500, in £1 shares; 6,350 shares have been taken up, and 6,000 of these have been issued as fully paid. The full amount has been called and paid on the remainder.

OXFORD ELECTRIC COMPANY (LIMITED).—The annual return of this Company, to April 19th, has been filed. The nominal capital is £100,000, in £5 shares, of which 6,586 have been subscribed for and allotted. The full amount per share has been called.

PHOSPHOR BRONZE COMPANY (LIMITED).—The annual return of this Company to April 12th has been filed. The nominal capital is £150,000, divided into 15,000 £5 Ordinary and a like number of Preference shares; 8,375 Preference and 7,335 Ordinary shares have been subscribed for and allotted, and the full amount per share called. The calls paid have realised £78,550; 1,156 shares in the Company have been forfeited.

PRINTING TELEGRAPH AND CONSTRUCTION COMPANY OF THE AGENCE HAVAS (LIMITED).—The annual return of this Company to January 1st was filed on March 28th. The nominal capital is £115,000, in £5 shares; 20,030 shares have been taken up, and of these 10,823 have been issued as fully paid. Calls of £3 per share have been made on the remainder, resulting in the payment of £9,554, and leaving £18,067 in arrears.

PUTNEY ELECTRIC SUPPLY COMPANY (LIMITED).—In reply to official requests for the filing of the statutory returns, the solicitors, on May 3rd, wrote stating that the Company was formed for the purpose of promoting an Electric Lighting Provisional Order. Nothing was done beyond giving the notice provided by the Standing Orders of the Board of Trade. The concern was registered on June 27, 1894, with a capital of £1,000.

RAILWAY ELECTRIC FOG SIGNAL SYNDICATE (LIMITED).—The annual return of this Company to September 4, 1894, was filed on April 27th. 18,000 shares, out of a capital of £25,000, in £1 shares, have been taken up, all of which have been issued as fully paid.

RANSOMES, SIMS AND JEFFERIES (LIMITED).—The annual return of this Company to April 25th is filed. The nominal capital is £500,000, in £100 shares. Of these 3,087 have been subscribed for, and a call of £50 per share has been made on 726 shares, and the full amount has been called on the remaining 2,361.

CITY NOTES.

AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).—Particulars will be found in our advertisement columns of the fourth drawing of Four per Cent. Mortgage Debenture bonds of this Company (115 in number) of £100 each. These debentures will be paid off at par on July 1st next, at Parr's Banking Company, and the Alliance Bank (Limited), Bartholomew-lane, London, E.C.

ALLGEMEINE ELEKTRICITATS GESELLSCHAFT (BERLIN).—The general meeting of shareholders of this Company voted unanimously for the increase of the original capital by two million marks (£100,000). This money is to be used for the building of new works. How rapidly this firm has grown is shown by the fact that at the end of 1889 only 664 hands were employed, whereas at present there are 2,200.

BLAKE AND KNOWLES STEAM PUMP WORKS (LIMITED).—It is announced that a drawing of 100 First Mortgage Debentures in this Company for redemption on July 1st next will take place at the offices of the Trustees, Executors, and Securities Insurance Corporation, on Friday, the 17th inst., at 11 o'clock.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended May 5th were £864, as against £887 in the corresponding period of 1894, being a decrease of £23. The total receipts for the half-year amount to £16,983, against £16,401 for the corresponding period of 18.4, an increase of £582.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of April, 1895, amounted to £1,942, against £1,742 in the corresponding period of last year.

ELECTRIC TRACTION.—In the prospectus of the Twin City Rapid Transit Company (Minneapolis and St. Paul, Minn., U.S.A.), for which subscription for $370,800 in Seven per Cent. Cumulative Preference shares is now offered to British investors, it is stated that the system of tramways consist of 225 miles, of which 219 miles are electric, and the remainder cable. During the last 10 years the growth of the system has been rapid and continuous, and the recent change of motive power from horse to electricity has brought increasingly satisfactory results, both to the public and to the Company. The total capital of the Company is $18,010,000. Lists close this day (Friday). The issuing house is Morton, Rose and Co., Bartholomew-lane, E.C.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of April amounted to £27,600. The total receipts from January 1st to April 30, 1895, were £95,600, as compared with £84,000 and £83,000 in the corresponding periods of 1893 and 1894 respectively.

ILLINOIS (U.S.A.).—It is stated that a new company has recently been incorporated in this State, with a capital of $5,000,000, under the title of the Metropolitan Electric Street Railway Company. The offices are at Chicago.

LIVERPOOL GAS FITTINGS COMPANY (LIMITED).—At the meeting of the shareholders of this Company, on Wednesday, Mr. J. Barkeley Smith, the Chairman, in proposing that a dividend for the year at the rate of £10 per cent. per annum, with a bonus of 1s. per share, free of income tax, be declared, said business had been comparatively quiet during the year. In regard to gas fittings, their business was undoubtedly quiet, and even dull, but they had an unusual number of orders on hand for electrical fittings. Mr. J. Lister repeated the statement he had made at former meetings, to the effect that the electric supply company, so far from injuring the gas company, had really increased the consumption of gas, and this statement was confirmed by Col. Robinson.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 5th inst. amounted to £1,148. The amount for the corresponding week last year was £874.

LONDON PLATINO-BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The seventeenth ordinary general meeting of the shareholders of this Company was held at the offices, Blomfield House, London-wall, on Monday, under the presidency of Mr. W. S. Andrews. The chairman formally proposed the adoption of the report. Mr. C. W. Earle seconded the motion, which was carried; and resolutions were afterwards passed declaring a dividend at the rate of £1. 5s. per cent. per annum (2s. 6d. per share) for the year, and re-electing the retiring Directors, Mr. John Coppen and Mr. Earle, and the auditors, Messrs. Deloitte, Dever, Griffiths and Co.

MORECAMBE ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The fourth annual meeting of the shareholders of this Company was held on Saturday, in private. The report showed a loss of £424. 14s. 5d., stated to be due to loss on supply of current consequent on the "scale system" of annual charges per lamp being found unremunerative. This has been (the Chairman stated) a serious mistake, and is to be abandoned forthwith in favour of supply by meter. The recent conviction for nuisance had necessitated the removal of the Company's premises to a non-residential part of the town, and for this it was proposed to raise £1,800 in preferential capital. The report and balance-sheet were adopted.

SOUTH AMERICAN CABLE COMPANY (LIMITED).—Notice is given that 63 Five per Cent. Mortgage Debentures of this Company were drawn on May 7th, and will be paid on or after June 30th next at the National Bank of Scotland, 37, Nicholas-lane, E.C.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee appointed yesterday (Thursday) a special settling-day in 2,475 Ordinary shares (Nos. 20,001 to 22,475) and 10,000 Six per Cent. Cumulative Preference shares (Nos. 40,001 to 50,000) in the County of London and Brush Provincial Electric Lighting Company (Limited), and have ordered the Ordinary shares (Nos. 1 to 22,475) and 10,000 Six per Cent. Cumulative Preference shares to be quoted in the Official List.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended 3rd inst., after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,891.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this Company for the half month ended April 30th are £2,607, as compared with £2,501 in the corresponding period of 1894. The transfer books of this Company will be closed from May 9th to May 22nd, inclusive.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 887. [No. 3. Vol. XXXV.] FRIDAY, MAY 17, 1895. PRICE SIXPENCE.

NOTES.

No doubt it is one of those things which could not be helped; but it is nevertheless to be regretted that when the Institution of Electrical Engineers is in possession of that extremely rare product, a good Paper by a good man, it should only be possible to devote a little over an hour and a-half to its discussion. Mr. MARK ROBINSON'S Paper, "On the Recent Development of the Single-Acting High-Speed Engine for Central-Station Work," literally teems with debatable matter, and throws down the gauntlet, although not with undue provocation, to the advocates of all other systems of steam practice. We hope, therefore, to see the supporters of and makers of slow-speed, horizontal, and ultra-high-speed engines do valiant battle next Thursday on behalf of their respective *protégés*. Unless, however, the ten-minutes rule is rigidly adhered to, it will be impossible to properly bring out all the various aspects of the other side of the question. Much as speeches filled with humorous irrelevancies contribute to the gaiety of nations and the enlivenment of debates which are as a rule none too inspiriting, the regular development of a good joke requires time, and we would suggest that on this occasion, being the last evening before the adjournment for the vacation, all jocularities be taken as said or sent in in writing to the Secretary of the Institution.

IN our "Correspondence" columns this week will be found a letter from Mr. MUSGRAVE HEAPHY, in which he states that the Phœnix Fire Office learn with surprise and amazement that the Institution of Electrical Engineers propose to revise their installation rules, and announces that the Phœnix Fire Office will have nothing to do with any rules, revised or unrevised, other than their own. We fail to see that there is any urgent call for this pronouncement. No one questions that the Phœnix Office, in common with other fire insurance offices, is the party most concerned in good house-wiring—more so even than the electrical industry in general, or the electric supply companies in particular. Again, no one questions the necessity for rules, or the many excellencies of those drawn up by the Phœnix Office. Indeed, if the proof of the pudding be in the eating, the Phœnix rules, judging by the absence of fires, are beyond criticism. Nevertheless they are, have been, and will be criticised, and there exist numerous other regulations mostly differing, it is true, but slightly from those of Mr. MUSGRAVE HEAPHY; and we may be permitted to anticipate that a Hybrid Committee composed of representatives of the fire offices, supply companies, Council of the Institution of Electrical Engineers, and Committee of the Electrical Trades' Section could draw up a more generally acceptable set of rules. It seems to us that the time has come when a single set of simple rules should suffice for such a territorially small portion of the globe as the United Kingdom. At any rate an attempt might be made. All the same it seems to us that too much noise is being made about wiring rules. One would think electricity were akin to dynamite.

OUR "Legal Intelligence" columns record the fact that the long fight between the Commercial Cable Company and Messrs. MUIRHEAD has ended in a victory for the latter, the Company agreeing to pay the patentees a considerable sum for the use of the American duplex patent during the remainder of its existence. By this result, it seems to us, substantial justice has been done.

THE universal electrodynamometer of Prof. KARL ZICKLER, a description of which we give in another column, appears to be one of the most successful attempts hitherto made to produce a single instrument which can be used as an ammeter, voltmeter, or a wattmeter, under very variable conditions. It is, however, questionable whether, in adapting the instrument to so many different functions, a sacrifice of convenience has not been made, which will more than counter balance the advantages secured. Of its utility as an ammeter, either for direct or alternating currents, there can be no doubt; and by the use of a number of coils a large range of sensitiveness is secured and a multiplication of instruments avoided.

WHEN, however, Prof. ZICKLER attempts to use the same instrument as a wattmeter, and, more especially, as a voltmeter, the sacrifice to compactness seems to us to be carried too far. In order to make his instrument suitable for current measurement up to 100 amperes, the torsion spring must be somewhat powerful, and this necessitates a large current when the instrument is used as a voltmeter, and there is consequently a large waste of power. This disadvantage is in itself a serious one; but it is of small importance compared with the effect it has on the accuracy of the instrument. A powerful spring demands a large turning moment of the coils, which, in turn, requires a large self-induction in the instrument. The

Digitized by Google

self-induction being high, and the resistance comparatively low, on account of the large current, the correction for self-induction becomes very high, at high rates of alternation; the volts in this instance for a given torsion angle varying from 600 with steady currents to over 900 at a periodicity of 100. With a periodicity of 133, such as is often used in America, the corresponding value of the volts would be 1,100, or nearly double the steady value. At this frequency, also, an error of 1 per cent. in the frequency would make about 0·7 per cent. error in the potential difference, which would render the instrument useless for accurate work.

The essential point to be borne in mind in designing a voltmeter on this principle is that the force between the coils must be very small. Under these circumstances the self-induction of the instrument can be made so small, and the resistance used with it so large, that the correction for self-induction becomes almost inappreciable at any ordinary periodicity. Two other important advantages are also secured, namely, the reduction of the power wasted in heating the coils, and the consequent admissibility of a resistance material of high specific resistance and low temperature coefficient, such as platinoid or manganin, thus greatly reducing the bulk of the resistance and the temperature correction. The same remarks apply to the wattmeter with even greater force so far as the self-induction of the voltmeter coil is concerned. As is stated in the Paper, the correction factor for alternate currents is dependent on the lag in both the voltmeter and main circuits, the latter of which cannot easily be determined. All this complexity could be practically eliminated by reducing the self-induction of the voltmeter coil.

At a recent meeting of the Liverpool Engineering Society Dr. Oliver Lodge read a Paper on "The Second Law of Thermodynamics," which we reprint this week, and he undertook to show that this law "is, after all, nothing more than enlightened common sense." But mechanical engineers, and with them our esteemed contemporary the *Engineer*, are not quite disposed to regard the matter in this light. In the discussion on Dr. Lodge's Paper, Prof. Hele-Shaw stated that he thought that physicists and engineers had different ways of regarding the same question; another speaker referred to Clerk Maxwell's little book on heat as an example of "what a physicist can do to fog an engineer"; and a third speaker thought that physicists ought to "let themselves down a little," so as to become intelligible to engineers. And yet Prof. Lodge had raised no new hypothesis, but had merely stated a well-established generalisation in clear and accurate language. All this pother raised by the engineers arises from the mistake of supposing that the second law of thermodynamics applies to the actual, realisable efficiencies of actual engines. It applies only to an ideal engine, which has not, and never can, be made. In the real engines it is all important what sort of working substance is used; in the ideal engine all substances are equally effective—just as in an ideal city it would not matter where one went out to lunch, while in cities as they are it matters much. Although with the most judicious management we can never raise the actual to the level of the ideal, it is none the less useful to know what the ideally best really is.

Some engineers think that the actual efficiency of heat engines is already often as high as, or higher than, the ideal set by the second law. Prof. Hele-Shaw asserts that "a good boiler will give an efficiency of more than 70 per cent.," and another engineer, while stating that "engineers reckon the efficiency of a steam engine differently from a physicist," confesses that the engineer's way is to "start with the temperature of *the steam in the boiler*, and so obtain the maximum efficiency possible in that way." The first of these gentlemen has surely forgotten that a boiler is only half a steam engine, and wants to ignore the part where the real thermodynamic work is done, while the second is just as anxious to have nothing to do with the furnace. Makers of steam engines and boilers have, of course, a perfect right to do this if they choose, but then they must not expect to be allowed by physicists to compare the "efficiencies" thus obtained with the efficiency given by the law of thermodynamics.

At a meeting of the Lighting Committee of the Liverpool Town Council on Monday, Sir Frederick Bramwell reported in favour of purchasing the undertaking of the Liverpool Electric Supply Company for £400,000. The paid-up capital of this concern amounts to some £250,000, and as its £5 shares stand at about 7⅝ their market value is over £380,000. So that when the loss of the 5 per cent. dividends and the voluntary nature of the surrender are taken into consideration, it will be seen that the shareholders will not be made rich beyond the dreams of avarice, though they will have been fairly dealt with.

Politics and sectarianism, especially of the village order, have done not a little in their time to embroil peace-loving folk. But if a Fareham ratepayer is to believed, electric lighting promises to become an equally potent cause of disturbance. Speaking at a recent meeting of ratepayers, held to discuss what steps should be taken to bring the pending litigation between the Fareham District Council and the Fareham Electric Light Company to an amicable termination, Mr. Dodds is reported to have said that "the electric light question had torn asunder friendships that had lasted for years, and men now passed each other in the street like dogs." What an excellent advertisement this sad state of things would make for, say, incandescent gas: Warranted to give n candles for n^{-x} cubic feet of gas and to destroy no friendships.

Cable Interruptions:

	Date of Interruption.
Latakia—Cyprus	Nov. 27, 1894.
Gibraltar—Tangier	April 24, 1895.

Institution of Electrical Engineers.—The following new members were admitted to the Institution at the last meeting:—Foreign member: Don R. Casado. Member: S. Bright. Associates: C. F. Fielding, A. Rutherford, and R. Wason.

Electricity on Board an Austrian War Ship.—The new Austrian coast defence vessel "Monarch," which was recently launched, is on the most modern principles. All movements

Digitized by Google

of the turret, as well as the supply of ammunition to the guns, are carried out electrically.

Lectures at the Electrical Standardising, Testing, and Training Institution.—On Tuesday, the 28th inst., Mr. James Swinburne will commence his usual course of lectures on "The Construction of Dynamos, Alternators, and Transformers" to the students of the above Institution.

The Meaning of the Recent United States Patent Decision. An extremely lucid and interesting article by Dr. Park Benjamin on the recent decision of the United States Courts as to the limitation of American patents by the expiry of *previously granted* foreign patents is to be found in the current number of the *Engineering Magazine*.

The Utilisation of Old Insulators.—The Belgian Postal Telegraph Department, not content with offering its discarded insulators for sale, offers suggestions for their use. An advertisement posted on the walls runs as follows, at least, so says our contemporary *L'Industrie Electrique* :—The insulators will be sold all together or in lots, as desired; they may be advantageously employed as park or garden-path borders.

Royal Society.—The following were some of the Papers down for reading before the Royal Society yesterday:—Prof. Ewing, F.R.S.: "On Measurements of Small Strains in the Testing of Materials and Structures." Prof. G. M. Minchin: "The Electrical Measurement of Starlight. Observations made at the Observatory of Daramona House, Co. Westmeath, in April, 1895. Preliminary Report."

Electrical Communication with Lightships.—In the *Standard* of the 14th inst., Mr. F. Higgins, of the Exchange Telegraph Company, writing on the "Sunk" system, claims that the method in question was one designed and recommended by himself, and described and illustrated in December, 1881, at which time numerous petitions were being presented to the Government from coast towns for the establishment of telegraphic communication with lightships.

More Electric Traction for Budapest.—The Budapester-Strassenbahn-Gesellschaft, which now works its lines by horses, is proposing to work its lines by electricity, and the Hungarian Board of Trade has given its provisional consent. The Company is required to build two generating stations and acquire 200 cars, which are to be so arranged that they can run with either overhead or conduit conductors. The overhead system will be provisionally permitted, but will have to be converted into a conduit system if the authorities require it. The capital required for the rebuilding of the lines is estimated at £1,050,000.

Southwark Bridge Explosion.—In the House of Commons, last week, Mr. Howard asked the President of the Board of Trade whether, having regard to the serious character of Major Cardew's report on the explosions which occurred on February 1st last on Southwark Bridge, he would state whether the City of London Electric Lighting Company had now taken the necessary measures so as fully to comply with the regulations imposed on them by the Board of Trade for the protection of the public. Mr. Bryce replied that the Company stated that on receipt of Major Cardew's report they at once began to take the measures recommended in the report.

Berlin Industrial Exhibition, 1896.—The contract for the lighting and the supply of current for power purposes of this exhibition has been placed with the "Verband Deutscher Elektrotechniker." The Verband, which has all the most important electrical engineering firms as members, undertakes the work at cost price, in accordance with a resolution passed some two years ago at the annual meeting at Cologne. A syndicate has been formed for the execution of the contract, and the following firms are on the Board:—Siemens and Halske, Allgemeine Elektricitäts-Gesellschaft, Gebrüder Naglo, Berliner-Maschinenbau Aktien-Gesellschaft and Union Elektricitäts-Gesellschaft.

Electric Track Welding Tests.—According to the *Electrical Engineer* of New York, the Johnson Company, of Johnstown, Pa., is making tests of a new process of rail welding. Formerly the work of making welds on street rail joints was accomplished from one car, which was burdened with all the machinery required for that kind of work. The Company, now, however, has a train of four cars. In one of these is placed a large dynamo, which is operated by the current taken from the trolley wire. The second car is known as the welding car, and the third as the grinding car. The fourth contains a storage battery. Formerly the great difficulty in making heavy welds on street roads was in procuring sufficient current. It is thought the storage battery will facilitate matters and serve to aid in doing the work better and with more dispatch.

Obituary.—At the last meeting of the Institution of Electrical Engineers reference was made to the death of Major-Gen. R. H. Stotherd, R.E., C.B., who was one of the original members of the Society of Telegraph Engineers, and served on its first Council. He was intimately connected with the early development of military telegraphy, and did a good deal of work in connection with torpedoes and other means of coast defence. Gen. Stotherd obtained his commission in the Royal Engineers in 1847, and from 1866 to 1871 he was Instructor in Electricity at Chatham. From 1873 to 1876 he was specially employed at the War Office as a member of a committee on torpedoes. For the last 32 years of his active service he was Director-General of the Ordnance Survey, and during that time took great interest in electrical matters. By his initiative, improvements were made in the method of depositing copper electrically.

Three-Phase Water Works at Canandaigua.—The *Electrical Engineer* of New York states that the village of Canandaigua, in New York State, has let recently the contract for the construction of a new water works system. The pumps will be operated by means of power electrically transmitted on the three-phase system of the General Electric Company, which Company will supply all the electrical apparatus. The power house will be located on the shore of Canandaigua Lake, and will contain one 100-kilowatt three-phase generator delivering current at 2,080 volts. The current will be transmitted to the pumping station nearly four miles distant, on the shores of the lake. The pump house will be occupied by two one-million gallon pumps, directly geared to 100 H.P. induction motors, wound for 2,080 volts, and revolving at 600 revolutions. The duplication of the pumping system has been determined upon in order that the work may be carried on continuously even should one pumping equipment break down. An automatic signal alarm will indicate at the power house when the reservoir is full.

The Periodic Law of the Chemical Elements—As the law of periodicity of the elements has been specially noticeable of late, in connection with argon, it may be of interest to mention three new points of discovery, in 1894, by which the probability of this law has become strengthened. The points are referred to in an article on "Progress in Physical Chemistry During 1894," by J. W. Rodgers, in *Science Progress* for the current month. (1) Töpler has found that the volume-change observed when a metal melts is a periodic function of the atomic weight; (2) Bailey has discovered that in an *even* series of elements the temperature of decomposition of an oxide is higher the higher the atomic weight, in *odd* series the reverse rule holds; and (3) Deeley observed that if the density of an oxide is divided by the atomic weight of the contained metal the quotient is a periodic function of the atomic weight. It is interesting to observe the steadiness with which the pile of evidence in support of one of Nature's most beautiful laws grows higher and higher every year.

Electric Traction for the Mersey Railway.—The Mersey Railway Bill was on Monday under the consideration of a Select Committee of the House of Lords, presided over by Lord Harris. The object of the Bill was to empower the Company to work their line by electricity and to raise additional capital to the extent of £200,000. The case for the promoters was that the line so far had not been a financial success. In order to rescue the Company from its present financial position it would be necessary to work the line by electricity. It was estimated that the working of the line by electricity would effect a saving of £14,000 per annum, and that the extra traffic would represent at least £10,000, making an increase of £24,000 in the present revenue. Mr. Allen Searle, for the last four years official receiver of the Company, anticipated that

Digitized by Google

they would get an increase of traffic if the railway was worked by electricity. Evidence was also given by Mr. A. Siemens and Sir D. Fox. The Chairman said the Committee would pass the preamble of the Bill On Wednesday the bill was ordered to be reported to the House.

Results of Electric Railway Operation in Connecticut.—At a recent hearing before the Railroad Committee of the Connecticut Legislature, counsel for the New York, New Haven and Hartford Railroad Company submitted a statement showing the losses in local passenger traffic, due to the competition of parallel electric lines. The falling off in traffic, says the *Street Railway Gazette* of New York, is even greater than has been generally realised, and in view of the fact the opposition to the further construction of competing electric roads is not surprising. The comparative statement shows the number of strictly local passengers carried by the steam road between the stations named during the period of the six months ending with February, 1894 and 1895, with the percentage of decrease for 1895, as compared with 1894; together with figures showing the approximate distance between these places:—

Six months.	1894.	1895.	Dec. per cent.	Miles.
Bridgeport and Stratford	23,547	7,068	69	3
N. Haven and West Haven	8,234	6,649	19	2

Municipal Purchase of Tramways.—Last week the case of the North Metropolitan Tramways Company v. the London County Council came before Mr. Justice Romer. In opening the case, Sir R. Webster said the action was brought to raise two important questions of law with reference to the rights of the Council to acquire the tramways of the North Metropolitan Company. The first point was whether the period of time had arrived when the Council could give the notice. A variety of undertakings and extensions had been amalgamated into one concern. The plaintiffs contended that the time for purchase did not run until 21 years from the last of the extensions which were amalgamated with and made part of the undertaking which the defendants had sought to buy. The next point, he said, was whether the defendants had a right to buy certain depots. The defendants' contention was that they were entitled to buy each part as it fell in. Mr. Finlay, on the other side, submitted that Section 43 showed that the plaintiffs' contentions could not be supported. The result of allowing the contention of the plaintiffs would be that each extension would repeal the period of purchase fixed with reference to the undertaking, which would be an absurdity. Mr. Justice Romer said he would reserve his judgment, but he did not feel any doubt as to what his decision would be. Judgment wili be delivered to-day (Friday).—The Bill promoted by the London County Council for powers to work London tramways has been passed by the Examiner of the House of Lords on all questions relating to standing orders. It is stated that the London tramway companies, who failed to defeat this measure in the Commons, intend to renew their opposition when the Bill comes before the Select Committee of the Lords.

Electric Power in Mexican Mines.—An interesting electric power installation is now under construction for the Cia. Anonima de Transmision Electrica de Potencia, located in the State of Hidalgo, some 100 miles north of the City of Mexico. The water is taken from the Arroyo de Regla, a mountain stream having a minimum supply of 1,500 cubic ft. per minute. A natural rock dam at a favourable point in the canyon impounds the water sufficiently to admit of its being diverted by a cut through the bluff into a canal, which follows mostly the contour of the mountain, a distance of a mile and a-half, a work which involved the cutting of seven tunnels, aggregating a total length of 1,200ft. through solid rock. From the terminus of the canal the water is carried to the power station through 1,700ft. of 30in. pipe, which affords a vertical head of 800ft., this being of varying thickness to correspond to the pressure at various points on the line, the lower portion being made of steel ⅜in. thick. The pipe line discharges into a receiver 40in. diameter by 75ft. long, with which the wheels are connected by lateral branches. The power station consists of five 40in. Pelton wheels of 400 H.P. each, coupled direct to the same number of 12-pole, three-phase generators at a speed of 600 revolutions, giving current at a pressure of 700 volts. Also two 24in. Pelton wheels, running at 1,700 revolutions, for driving the exciters. The step-up transformers are wound for a ratio of 1 to 15, making the line potential a little over 10,000 volts at the generator end. There are three transformer sub-stations in which air-blast transformers are to be used. Pelton differential governors are attached to each wheel for the purpose of regulation. This station is to supply power to the mines of the Rio del Monte Company, a most extensive mining organisation employing upwards of 8,000 men. The power is to be used for operating mining machinery, such as stamp mills, crushers, pumps, hoists, ventilators, &c., &c. The mines of this Company are located within a radius of 20 miles, the maximum distance of power transmission being 23 miles, and the mean distance about 18 miles. Various other mines in the vicinity will also be supplied with power from this station, and the City of Pachuca also furnished with light.

Royal Society Candidates.—The following are the qualifications of those of the 15 candidates recommended by the Council of the Royal Society for election who have done work of electrical interest. We are indebted to *Nature* for these particulars:—

Ernest Howard Griffiths, M.A., Private Tutor. Author of the following Papers:—"On the Comparison of Platinum Temperatures with the Kew Standard" (Rept. of Committee on Electrical Measurements, Brit. Assoc., 1890); "On the Determination of Certain Boiling and Freezing Points" (*Phil. Trans.*, 1891 A); "The Electrical Resistance of Platinum Wire at Absolute Zero" (*Phil. Mag.*, December, 1892); "On the Determination of Low Temperatures by Platinum Thermometers" (*Proc. Camb. Phil. Soc.*, Vol. VIII., Part I.); "On the Increase in Resistance of a Conductor when Transmitting a Current" (*ibid.*, Vol. VIII., Part I.); "The Mechanical Equivalent of Heat, together with an Investigation into the Changes in the Capacity for Heat of Water" (*Phil. Trans.*, 1893 A); "The Boiling Point of Sulphur, together with a Method of Standardising Platinum Thermometers," jointly with Mr. Callendar (*Phil. Trans.*, 1891 A). *Supplementary Certificate.*—Appendix to the communication entitled "The Mechanical Equivalent of Heat" (*Proc. Roy. Soc.*, Vol. LV., 1893); "A Method of Joining Glass and Metal Tubes" (*Proc. Phil. Soc. Camb.*, 1893); "The Measurement of Temperature" (*Science Progress*, 1894); "The Influence of Temperature on the Specific Heat of Aniline" (*Phil. Mag.*, 1895); "The Latent Heat of Evaporation of Water" (read Royal Society, January, 1895).——Henry Capel Lofft Holden, Major, Royal Artillery. In India, from 1877-84, he carried out a number of experiments in telephony and telegraphy for the Indian Government. Since 1885 he has been in charge of the Department for the proofs of Naval and Land Service Ordnance, and Gunpowders, and for experiment work connected therewith, and has invented and constructed many pieces of apparatus connected with the science of artillery, as well as with electrical and scientific research. Amongst those which have been publicly exhibited are his devices in connection with the chronograph, for measuring the velocity of projectiles; an extremely accurate and sensitive hydrometer for measuring the variations of the density of the acids in the electrolyte accumulator cells (exhibited Royal Society, 1887; *see* also Paper before Iron and Steel Institute, 1891); a high-speed chronographic pen for recording minute intervals of time by electromagnetic means; various instruments for making accurate and rapid tests of the pressure and current in direct-current circuits, and in alternating-current circuits of both high and low frequency (some exhibited Royal Society, 1892); an instrument for rapidly ascertaining the E.M.F. and resistance of a galvanic cell (exhibited Royal Society, 1893); a compact moving coil galvanometer adapted to universal purposes, which was employed by Profs. Dewar and Fleming in their researches on the resistance of metals, and is used in the recording pyrometer of Prof. Roberts-Austen. He was deputed by the Commander-in-Chief to write the electrical sections of the Paris Exhibition of 1889, the Frankfort Exhibition of 1891, and the Chicago Exhibition of 1893, and furnished the Government with most valuable reports.——George M. Minchin, M.A. (Dubl.), Professor of Mathematics in the Royal Indian Engineering College, Cooper's Hill. Author of the following treatises:—"Statics," "Uniplanar Kinematics," and "Hydrostatics." Also of the following Papers:—"Astatic Equilibrium of any System of Forces, treated by Quaternions" (*Proc. Lond. Math. Soc.*); "The Absolute Sine Electrometer" (*Nature*, *Electrical Review*, &c.); "Researches in Photo-Electricity" (*Proc. Phys. Soc.* and *Phil. Mag.*); "Impulsion Cells" (*Electrician*, *Proc. Phil. Soc.*); "Seleno-Aluminium Cells and the Electromotive Forces of Starlight" (*Astronomy and Astro-Physics*); "The Magnetic Field of a Circular Current"; "The Magnetic Field close to the Surface of a Wire Carrying a Current" (*Phil. Mag.*, *Proc. Phys. Soc.*)

THE ZICKLER UNIVERSAL ELECTRO DYNAMOMETER.

The principal measurements which the electrician requires to make are those of resistance, current, potential difference, and electrical power. For the measurement of the three last quantities a large number of instruments are required when the measurements are made with any accuracy. This multiplication of instruments arises, in the first place, from their limitations of range; secondly, from the different quantities measured; and lastly, from the nature of the currents employed, continuous and alternating.

The foregoing facts, says Prof. Karl Zickler in a pamphlet, of which this is an abstract, induced him to devise an instrument which should be capable of measuring current strength, potential difference, and electrical power, either continuous or alternating, between wide limits. This instrument he calls a universal electrodynamometer.

The principle of this instrument, as in most other standard instruments, is the measurement of the force due to the mutual action of two currents. The author remarks that Lord Kelvin has devised a modification of his ampere balance, known as the composite balance, which measures current potential difference and watts between wide limits. This instrument, however, requires an auxiliary current in the movable coil, and hence is unsuitable for alternating currents. It is also desirable that in any standard measuring instrument for alternating currents the mutual induction between the coils should be negligible, otherwise the corrections, when using the instrument as a voltmeter or wattmeter, become very complicated.

The instrument, therefore, consists essentially of two coils at right angles to each other, the moment of the force between them being measured by the torsion of a spring. For current measurements the fixed and movable coils are connected in series and the current passed through them. Then

$$J^2 = C^2\phi, \text{ or } J = C\sqrt{\phi},$$

where J is the current, ϕ the torsion angle, and C the dynamometer constant. The same formula holds for alternating currents where $J = \sqrt{\text{mean-square}}$ of the current.

For potential difference measurements the fixed and movable windings are connected in series with each other, and with an external non-inductive resistance to the points whose potential difference is to be measured.

In this case $\delta = C_1\sqrt{\phi}$, where δ is the potential difference and C_1 the dynamometer constant.

For alternating currents

$$\sqrt{\text{mean } \delta^2} = C_1\sqrt{1+\lambda^2}\sqrt{\phi} = C_1{}^1\sqrt{\phi},$$

where

$$\lambda = \frac{\pi p L}{W},$$

p being the number of alternations per second,
L the self-induction of the instrument in henrys.
W the total resistance of the circuit.

The quantity λ can be reduced by making L small, in which case the correction factor $\sqrt{1+\lambda^2}$ will be nearly unity. For power measurements one of the windings is connected to the main circuit, so that the whole current passes through it. The other winding is connected in series with a non-inductive resistance, to the points between which the power is to be measured.

In this case power $= J\,\delta = C_2\,\phi$.

For alternating currents it has been shown that

$$\text{Mean }(J\,\delta) = C_2\,\frac{1+\lambda_1{}^2}{1+\lambda_1\lambda_2}\,\phi,$$

where

$$\lambda_1 = \frac{\pi p L_1}{W_1} \text{ and } \lambda_2 = \frac{\pi p L_2}{W_2},$$

L_1 and W_1 being the self-induction and resistance of the voltmeter circuit, L_2 and W_2 those of the main circuit.

The correction factor $\dfrac{1+\lambda_1{}^2}{1+\lambda_1\lambda_2}$ can in this case be reduced to unity when $\lambda_1 = 0$ or $\lambda_1 = \lambda_2$.

Description of the Instrument.

A general view of the instrument is given in Fig. 1. The movable windings which surround the fixed coils consist of two parts, one of which is a copper frame of 35 sq. mm. cross-section, the ends of which dip into mercury cups i_1 (Fig. 2). The second part of the winding consists of 60 turns of 1·15mm. insulated wire wound on the copper frame, the ends of which dip into the mercury cups a_1. The movable coils can be raised and clamped by a lever which lifts the coils against a cone.

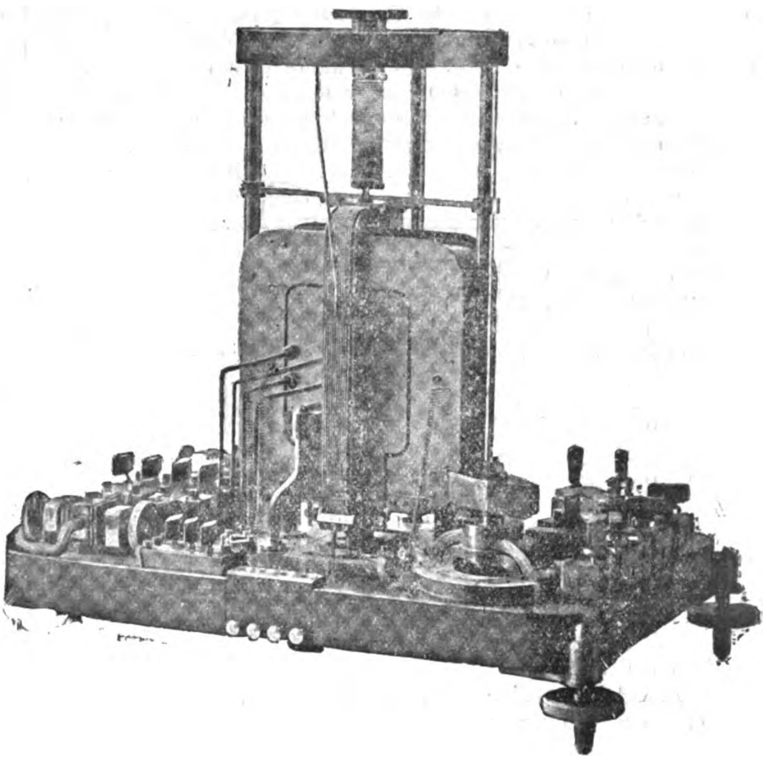

Fig. 1.

The coils, instead of being suspended by a filament (as in a Siemens dynamometer) which is liable to break and alter the constant of the instrument, rest on a pivot, thus securing perfect constancy of control. A pointer is also attached to the coil. The torsion spring is attached to the coil, and to a torsion

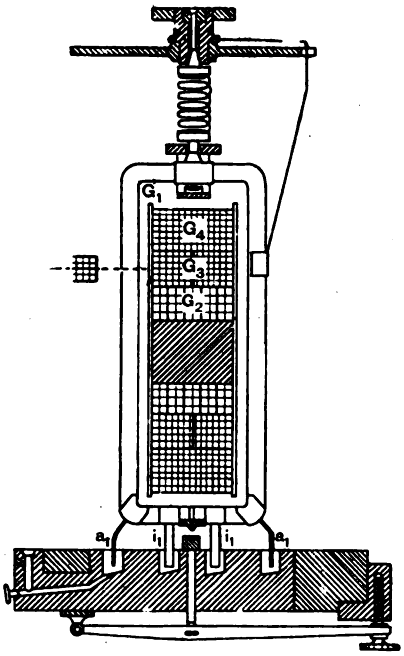

Fig. 2.

head and pointer moving over a dial in the usual way. The mercury cups, shown in plan in Fig. 3, are of such dimensions as to carry the maximum current without heating, and have a device for filling and emptying them without disturbing the instrument. This is effected by holes drilled horizontally in the base to the bottoms of the cups, the external openings

Digitized by Google

being closed when required by small iron stoppers, i_2 and a_2. Vertical holes, with cups i and a, are also made, communicating with the former tubes. The cups can be filled by pouring mercury into the cups i or a, and emptied by withdrawing the plugs. The level of the mercury in the cups is kept constant by small overflow openings into the cups i and a. The current passes to the mercury cups by a commutator K (Fig. 3), which is capable of short-circuiting or reversing the movable coil circuit. In all direct-current measurements the readings of the torsion angle are taken with the current flowing in the two directions in the moving coil. The mean of these readings is taken as the true reading of the instrument.

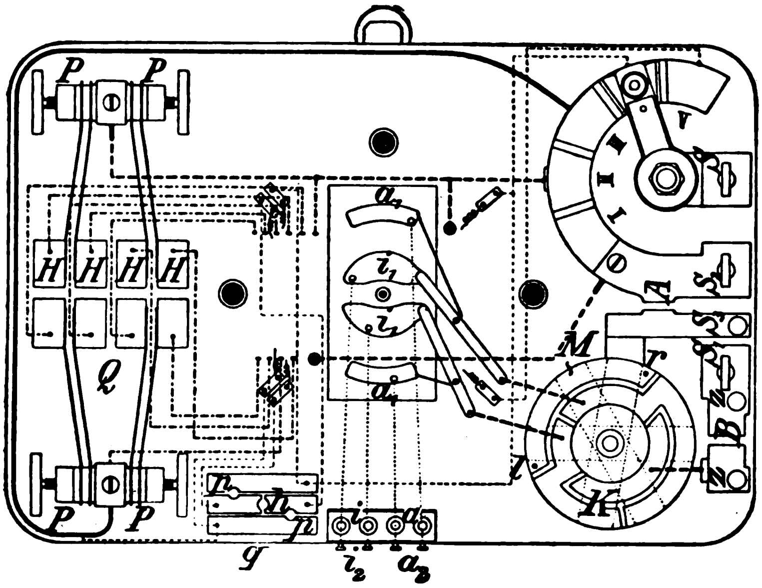

Fig. 3.

The fixed circuits consist of several windings of different cross-sections and different numbers of turns. The first part, G (Fig. 2), consists of four turns of copper tape, 1·5mm. thick and 35mm. broad, which form the flanges of the coils. The ends of this circuit are connected to the contacts I. and II. of the five-way switch, shown in Fig. 3. On the interior of the coils there are first five coils, G_2, each of 30 turns of copper strip 2mm. by 2·7mm. wound side by side, the ends of which are connected to the plug switches H (Fig. 3). By altering the arrangement of the plugs the coils can be put all in series, or, by contact pieces from the terminals P, in parallel. The terminals P are connected to the contacts II. and III. of the switch.

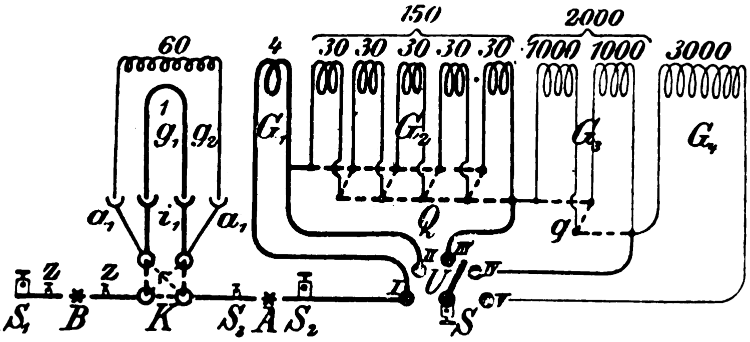

Fig. 4.

In this manner the coils can be arranged so as to give 30 turns of a total cross-section of 27 sq. mm, or 150 turns of 5·4 sq. mm. Outside these coils are two, G_3, of 1,000 turns of 0·45 mm. double silk covered wire, which can be put in series or parallel by a small plug switch q, and connected to contacts III. and IV. of the main switch. Lastly, there is a single coil, G_4, of 3,000 turns of the same wire, connected to contacts IV. and V. The connections are made to the instrument by a number of terminals, S, S_1, S_2, S_3, $z_1 z$, the arrangement of which can be seen on the diagram.

In using the instrument for current measurements the commutator is set to the position M (Fig. 3), the switch on contact I., and plugs are inserted in the positions A and B. The circuit is then joined to the terminals S and S_1. The current (*see* Fig. 4) then flows from S to I, A, K, B, and leaves by S_1, no coil of the instrument having been traversed. One pair of mercury cups having been filled, according to the magnitude of the current to be measured, the switch is set to one of the contacts I. to V., until a convenient sensitiveness is obtained, when the commutator is set in one direction. The reading is taken in this direction, and also when the commutator is reversed, and the current known from the mean of these readings and a constant depending on the arrangement of the coils used. There are eight constants, varying from 0·0211 to 5·97, which, for limits of angle of from 20deg. to 360deg., give as the range of the instrument, for direct and alternating currents, 0·094 ampere up to 113·3 amperes.

For potential difference measurements the commutator is set to the mark M, the switch on contact V., and the plug switches in series. The mercury cups a are filled, the plug removed from the point B, and the terminals $z z$ connected to the terminals of one of the non-inductive resistances used with the instrument. The number of turns in the circuits consists then of 5,154 turns on the fixed coil, and 60 turns on the movable coil, the total resistance of which is 223·43 ohms, which is made up to 250 ohms by one of the resistance coils. Five other resistance coils are used, each of 250 ohms. By the use of different combinations of these coils, and of the fixed dynamometer coils, a range of from 4·3 to 600·5 volts is obtained with continuous currents. The current when measuring 600 volts is 0·4 ampere. A correction has in this case to be made for temperature, which correction varies from 0·38 per cent. per 1°C. for the copper coils to 0·068 per cent. for the material used for the resistance coils. The coils are so arranged that no observable heating is caused by the current.

For alternating currents the correction for self-induction has also to be made, the value of which for the whole arrangement of coils is 2·76 henrys. The potential difference required for a to torsion angle of 360deg. alters from 600·5 with steady currents 661·6 at 80 alternations per second, and 917·8 at 200 alternations.

For power measurements the mercury cups a are filled, the plugs withdrawn from A and B, and the resistance connected to $z z$. The switch is set at contact I., the main circuit connected to the terminals S and S_2, and the points between which the power is to be measured to the terminals S_1 and S_3. Greater sensitiveness can be obtained by altering the position of the switch. The readings are then taken in the same manner as with a Ganz wattmeter, the corrections for temperature and self-induction having to be made. The instrument is then capable of measuring power between the limits of 14 and 56,376 watts.

When the 60 turns on the movable coil are used in the shunt circuit, with the smallest possible external resistance and highest periodicity (200 alternations per second), the value of λ_1 is 0·002 and of λ_2 0·000004. Hence, in this case, the value of λ_2 must be 5, in order that the correction factor should differ 1 per cent. from unity, which will be seldom the case.

The foregoing remarks show that this universal instrument is capable of measuring current, potential difference, and power both for direct and alternating currents, under a great variety of circumstances. The construction of the instrument precludes the possibility of any alteration of the constant with time, and during the eight months the instrument has been in use no variation of any kind has been detected. The reversing of the current in the moving coil eliminates any errors which might arise from external magnetic fields. Any change in the direction of the instrument relatively to the earth's magnetic meridian produces no appreciable change, the field of the instrument being exceedingly strong compared to that of the earth.

THE EDMONDSON "ZERO-TORQUE" METER.

At the last meeting of the Institution of Electrical Engineers Mr. Joseph Edmondson, of Bradford, exhibited and explained an ingenious electricity meter of the dynamometer type.

The meter, a general view of which is given in Fig. 1, is nothing more than the well-known Siemens dynamometer, combined with mechanism for measuring and integrating at short intervals the torque excited on the moving coil by the current going to the lamps. The motion of the moving coil is limited to an arc of less than 1deg., and the use of a durable steel-wire suspension, instead of the delicate suspension of the ordinary dynamometer, is thus rendered possible. A torque of about 90deg. is given to the usual spiral spring every two minutes by a reciprocating quadrant, or "mangle-wheel," driven by a vibrating motor consisting of a magnet and its armature, the motor being controlled by a small gravity-driven pendulum, starting automatically and having a sparkless contact, due to the use of a condenser and a resistance, as in the Oulton-Edmondson clock meter of 1893. The action of the instrument is made plain by Figs. 2 and 3, in which A is an arm pivoted at G, carrying a click working into a ratchet-wheel, and driving the registering train. It receives a reciprocating motion

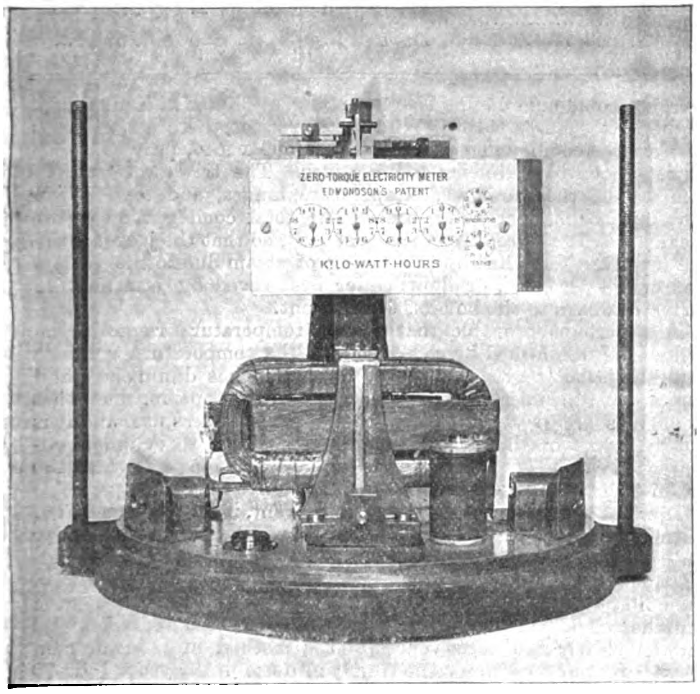

Fig. 1.—General View of the Edmondson Meter with Case removed.

from the vibrating motor. Fixed on its arbor is the arm B carrying the steel pin C. The flat steel stop D, which is on an arm projecting from the moving coil of the dynamometer, is free to move between the stops E and F. When the current is *nil* the stop D remains against the stop E, as in Fig. 2. In this position the pin C comes down upon it at each vibration, and the arm A is thus prevented from vibrating far enough to take a tooth of the ratchet-wheel. The registering is therefore *nil.* But when the moving coil of the dynamometer is deflected by the current the stop D moves to the right, and it assumes the position shown in Fig. 3. The pin C can now descend into the space between the stops D and E, and the arm A can vibrate to its full extent, and the registering proceeds. This continues until the reciprocating quadrant, or "mangle-wheel," in its motion to the left, acting through the spiral spring, exerts on the moving coil of the dynamometer a torque equal to that exerted by the current, brings the stop D back to the position shown in Fig. 2, and stops the registering. This action is repeated with each reciprocation of the "mangle-wheel." As the period during which the registering proceeds is *exactly proportional* to the torque exerted by the current on the moving coil of the dynamometer, the diagram of registration is a straight line. A 25-ampere meter will register from one-tenth ampere upwards. The total current required for the

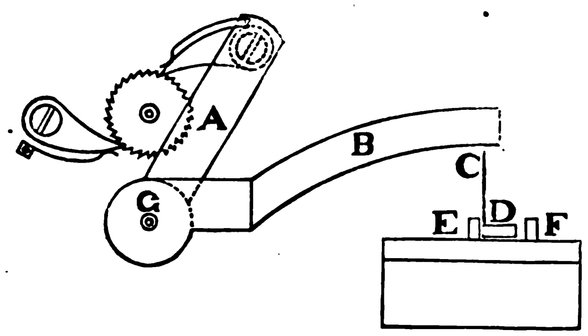

Fig. 2.

shunt circuit and the vibrating motor never exceeds, and is generally less than, two-hundredths of an ampere. The moving coil of the dynamometer, being in the centre of a cylindrical

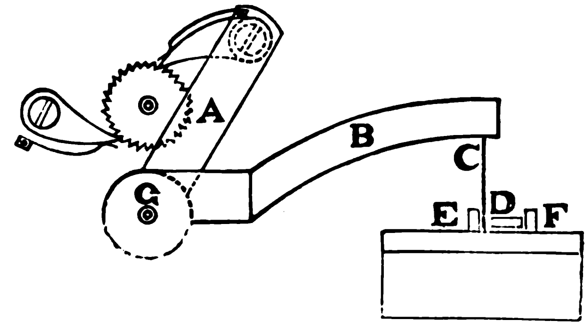

Fig. 3.

iron case, is shielded from external magnetic influence. The meter is calibrated to read direct in kilowatt-hours with a constant of 1.

THE DEVELOPMENT OF THE EXPERIMENTAL STUDY OF HEAT-ENGINES.*

BY PROF. W. C. UNWIN, F.R.S.

(*Concluded from page 50.*)

The Experimental Theory.

Hirn and the Alsatian School.

A year or two before Isherwood began his experiments, an Alsatian engineer, M. Hirn, had discovered and measured cylinder condensation. Hirn's father was artistic designer to a factory where printed calicos were made, and Hirn was at first in charge of the chemical laboratory of the factory. His first independent commercial adventure was in 1855, when he introduced mineral oil obtained in Alsace for lubricating purposes. One of his earliest scientific Papers was an account of researches on the friction of lubricated surfaces, which was refused by more than one scientific society, and since its publication remained little noticed. In this Paper results quite recently obtained are anticipated, and it is still one of the most valuable treatises on friction. The chief interest of Hirn's life was in purely scientific research, especially investigations of some of the most abstruse physical problems. The study of the steam engine, begun with a view of verifying Joule's discovery, was merely an interlude in a series of investigations, mostly dealing with more abstract departments of science. But Hirn formed a school of engineers devoted to the carrying out of experiments on the steam engine. He formulated the methods of engine testing adopted almost without change ever since. He brought to the analysis of the results an extremely acute intellect. He was the first to realise that the complexity of the actions in a steam engine was so great that a purely rational theory was

* The "James Forrest" Lecture, delivered before the Institution of Civil Engineers, May 2nd.

Digitized by Google

impossible, and that the engine could only be studied usefully by (to use a phrase of Prof. Cotterill) checking theoretical conclusions step by step by reference to experiment.

Joule's discovery attracted Hirn's attention, and he set to work in 1854 to verify by an exact engine test, whether the difference between the heat received by an engine and discarded in the condenser was the equivalent of the work done. His two most important memoirs relating to the steam engine are, a memoir on the utility of steam jackets in 1855 to 1856, and another on the use of superheated steam in 1857. In these researches he devised a method of accurate engine tests, involving the measurement of all the quantities of heat received by or rejected from the engine, which, with hardly any change at all, is the method of accurate engine testing adopted ever since. Under his influence and direction, engine tests were carried out in Alsace for many years, and the results exactly analysed. It may be recalled that the admirable series of engine tests, the first tests in which the heat quantities were accurately measured in this country, which were made by Mr. Mair Rumley, and described in three Papers on "Independent Engine Tests" in the *Proceedings* of this Society in 1882, 1885 and 1886, were trials carried out strictly in accordance with Hirn's methods.

As with Lord Kelvin, so with Hirn. It was the recognition of an apparent conflict of Joule's discovery with Carnot's law which first attracted his attention. It was the attempt to determine whether part of the heat supplied to an engine disappeared as work which determined the form of his trials. His experiments of 1854 showed that "heat in a steam motor is not only dispersed, but actually disappears, and the power obtained is exactly proportional to the heat which disappears as heat to reappear as motive power." Some rather later and more careful experiments enabled him to verify Joule's equivalent by the actual results of a large engine test to an accuracy of about 1 per cent.

Hirn's heat measurements in the engine trials of 1854-6 showed the important and even unaccountably large influence of the steam jacket on the steam consumption. Its effects could not in any way be explained, as merely the arrest of external radiation for the decrease of heat losses in the engine proved to be larger than the heat yielded to the cylinder by the jacket. It was in studying the action of the jacket that Hirn came to perceive, and before anyone else, to directly measure the initial condensation of steam in the cylinder.

The following are some results obtained a few years later by Hirn and Hallauer on a Corliss engine. Working without a jacket, the initial condensation was 62·3 per cent. The proportion of water in the steam at release is as 41·4 per cent., so that 20·9 per cent. at least was re-evaporated during expansion. Working with a jacket the initial condensation was 46·5 per cent., or 16 per cent. less than in the unjacketed trial. Further, the proportion of water present at release was only 15·3 per cent., so that 31·2 per cent. had been evaporated during expansion. Hence the gain from the jacket in those cases where it produces a considerable effect arises in two ways. The prejudicial initial condensation is considerably diminished, and more heat is given back from the cylinder wall during expansion when it is partially used in doing work, and less during exhaust when it does no useful work.

The discovery of initial condensation and the proof of the powerful action of a small amount of heat transmitted from the jacket both pointed to the conductivity of the cylinder wall as the cause of the large waste of steam which the constructors of the rational theory had neglected. The cylinder is cooled during expansion, and stil more during exhaust by an action analogous to internal radiation to the condenser. Before any work can be done in the next stroke, the wall has to be re-heated by condensing fresh steam. The extreme facility with which steam yields or abstracts steam by condensing and evaporating, accounted for the rapidity of the action. The magnitude of the condensation increases with the range of temperature to which the cylinder wall is subjected. It is larger in condensing than in non-condensing engines, and larger with high ratios of expansion.

Some time ago I ventured to say that there was no trustworthy engine test which showed that the consumption of steam with a jacket is greater than without a jacket. I believe that is still true, but undoubtedly the economy due to the jacket varies in different cases from 30 per cent. to very nearly zero. Roughly, the jacket is more useful with small engines than with large; with slow engines than with fast engines; but all this amounts to little more than saying that the jacket is most useful in those cases where the initial condensation is largest. Just in proportion as the engine, whatever its type, is of the highest class and most scientific design, the jacket is less useful. No one probably designed better simple engines than Corliss, and Corliss did not use jackets. In an experiment by Delafond on a large Corliss engine at Creusot, the jacket effected an economy of only 2 per cent. The same rule holds with compound engines. Hirn found an economy of 25 per cent. due to the jackets in a Woolf engine tested in 1855, but since

Per cent. of water at release	25	35·0	13	12·0	21
Per cent. re-evaporated during expansion	5	1·0	...	...	4
Per cent. condensed during expansion	...	...	13	5·5	...

then the compound engine has been improved, and the advantage of the jacket is less. Prof. Witz made very accurate experiments with a large compound engine of about 600 I.H.P., provided with jackets both to cylinders and receiver. The trials were strictly comparable, the pressures, temperature ranges, and total power developed being nearly the same. The total condensation in the jackets was 12 per cent. of the steam used, so that the jackets were not inactive. Yet the absolute saving of steam due to the jackets was only 4 per cent., or allowing for heat saved by returning the jacket drainage to the boilers, 6·6 per cent.

It is perhaps probable that as the temperature range in the cylinder is diminished by compounding, the temperature gradient from the jacket to the interior of the cylinder is diminished, and the rate of transmission of heat decreased. It appears, then, that as engines are better designed, the jacket is of less use, and it is not by means of the jacket that the waste due to cylinder condensation can be got rid of, or the highest economy of which the steam engine is capable reached.

The jacket reduces, but it does not prevent, initial condensation. Hirn looked for some more powerful way of heating the cylinder wall without causing condensation; he found it in superheating. He constructed in 1855 a superheating apparatus in the flues of the boiler at Logelbach, which still exists. The experiments with superheated steam were carried out between 1855 and 1856, and showed clearly the effectiveness of the method in reducing condensation. Superheating came largely into use in the years 1860-70 in this country in marine engineering practice, having been introduced here by John Penn. In every case in which it was used an economy of coal was realised. Generally the economy amounted to from 15 per cent. to 20 per cent. It was ascertained that this was due strictly to economy of steam, and not to the utilisation in the boiler of heat previously wasted. But the use of superheated steam in this country was gradually abandoned, partly, no doubt, from some practical difficulties, but chiefly, I believe, because practical engineers had no clear idea why superheating should produce so large an economy, and they were not indisposed to abandon a complication the action of which they could not satisfactorily explain to themselves.

In Alsace, superheating has never been entirely abandoned, and during the last ten years hundreds of boilers have been supplied with superheaters. So far as I can ascertain, no difficulty arises in using steam superheated to 500°F., and in good and large engines the steam consumption is reduced when the superheating amounts to 100deg. by 15 per cent. on the average. I have no doubt myself that superheating will be largely used again. The practical difficulties exist, but they are not insuperable.

No possible improvement of the steam engine, of which we have any knowledge at this moment, offers anything like so great a chance of important economy as the re-introduction of superheating, and especially of superheating to at least 100deg. or more above the saturation temperature of the steam. I obtained in Alsace, on a very good 500-H.P. compound mill engine, with jackets and every appliance for economical working, an economy of 15 per cent. Mr. Mair Rumley has fitted a superheater to a Babcock

Digitized by Google

boiler supplying a triple engine, and has obtained an economy of 10 per cent. In both cases the economy is economy of steam, and therefore is not due to any increase of boiler surface or increase of efficiency in generating the steam. Lately Prof. Schröter, of Munich, has been experimenting with a small special compound condensing engine of only 60 I.H.P. running at the moderate piston speed of 380ft. per minute, and with the not excessive boiler pressure of 165lb. per square inch. The high-pressure cylinder is not jacketed. The low pressure is jacketed with receiver steam. In this case, in a tube superheater of a rather special construction, in the uptake of the boiler the steam is superheated to 670°F., or nearly 300deg. above the saturation temperature corresponding to the pressure. In two trials of six and eight hours' duration, periods quite long enough for accurate determination of results with so accomplished an observer as Prof. Schröter, the consumption of steam was only 10·2lb. per indicated horse-power-hour, and the consumption of German coal of moderate quality only 1¼lb. per indicated horse-power-hour. The steam consumption is the lowest on record for any engine of any type or size, and is very remarkable for so small an engine.

It is often argued that as very little heat is required to superheat steam it cannot produce much effect. The answer is that a small amount of heat rightly applied in preventing initial condensation produces a disproportionately large effect. That is consistent with the strictest principles of thermodynamics. In the Schmidt engine only 8 per cent. of the heat was used in superheating the steam, and to this 8 per cent. the remarkable economy is due. In a steam-jacket acting well, about 12 per cent. of the steam used is condensed, and to this 12 per cent. the advantage of the jacket which often reduces the amount of steam used in the cylinder by 20 to 30 per cent. is due. But the heat from a jacket is much less efficiently applied than the heat taken direct to the interior of the cylinder by superheated steam and used primarily in maintaining the temperature of the admission surface. Further, the quantity of superheat brought into the cylinder in a given time increases with the speed of the engine while jacket-heat diminishes in effect as the speed is greater. The action of the superheated steam is shown clearly enough on the indicator diagrams. In my own trials in Alsace the wetness of the steam at cut-off in the horse-power cylinder with jacket, but without superheating, was 35 per cent., with steam superheated 100deg. it was only 15 per cent. In the trial with the Schmidt engine there was no moisture at cut-off in the horse-power cylinder, and the steam remained dry nearly to the end of the stroke.

Conflict of the Rational and Experimental Theories.—Zeuner, Hirn, and Hillauer.

On the appearance of Isherwood's researches, in 1863, the discrepancy between the rational theory and the results of experiment was recognised by Rankine and others. But the conditions of cylinder condensation are so complex that for a long time the more theoretical writers practically ignored both Hirn's and Isherwood's results. Zeuner, perhaps, had pushed the rational theory to the furthest limit of detail and with the greatest insight into practical conditions. But it was not till 1881 that he began to explicitly admit the largeness and importance of the condensing action in the cylinder. Zeuner then was disposed to attribute initial condensation to the presence of a permanent and not inconsiderable mass of water in the clearance space of the engine. No doubt it is simple analytically to deal with the thermal changes of the steam plus a given mass of water than with the thermal changes of steam, water, and a varying area of solid cylinder wall. In opening a discussion with Hirn, in 1881, Zeuner wrote that if the presence of water in the clearance space was conceded the Alsatian calculations would be greatly shaken, and "the enormous influence which they attributed to the cylinder wall would in future be attributed in part, perhaps chiefly, to the water in the clearance space." He thought it conceivable that in certain cases the whole of the initial condensation was due to water in the clearance space. There thus arose a rather angry controversy which has been summed up in the question, "Is it water or iron?" I do not know that this controversy has been as yet completely decided, or that perhaps an absolute decision is possible. I cannot help thinking that Hirn, with the clearness of view due to his experimental work, had on the whole the best of the controversy, and I do not know that anything better or more instructive can be said than the words in which he finally summed up his position. "We recognise," said he, "that the interpretation of the Alsatians differs from that of M. Zeuner, not at all in that it denies the possible presence of water in the cylinder (we are not so hydrophobic), but in that it admits that that water varying in quantity is presented only temporarily, is carried away and renewed stroke by stroke, and acts chiefly as the medium between the steam and the cylinder wall. In the Alsatian explanation the action of the water raises the thermal action of the sides. In Prof. Zeuner's view the water is permanently present and acts independently of the cylinder sides."

We may note that Mr. Donkin has been able to show, by direct thermometric observations, a considerable fluctuation of temperature in the innermost layer of the cylinder wall, and that, more lately, Prof. Carpenter, of Sibley College, has obtained photographic records of the fluctuation of temperature by using a thermopile and a recording galvanometer.

Recent Experiments—Willans.

It has been quite impossible in this lecture to do more than select one or two of the most important of the experimental investigations during the last 50 years. But I should not like to omit all reference to the two series of experiments of the late Mr. P. W. Willans. Mr. Willans' work is, no doubt, well known to all steam engineers, and needs no detailed description. However purely practical the object Mr. Willans had in view, his experiments were made in the true spirit of scientific research. No trouble was too much to secure accuracy to the last decimal, no possible cause of error was so trivial that its investigation was reckoned unnecessary. A few experimenters—Isherwood, Gately and Kletsch, and others—had made experiments on a methodical system; varying a single factor at a time. Willans carried out the method of experiments in series, on a scale which, till he proved that it could be done, no one would have supposed possible. There is a series of non-condensing, and a series of condensing trials; in each there are trials of simple, compound, and triple engines; and for each of these again, trials with initial pressure varied, with expansion varied, and with speed varied. The results tabulated in the clearest way form a quarry of scientific data, but at present in the main an unworked quarry. Perhaps that statement will seem surprising, and of course I am expressing only my own view, for which I claim no infallibility. What Mr. Willans might have done had he been spared, it is impossible to say. He had the most active mind and the widest experience devoted perhaps at any time to the study of steam problems. But so far as his Papers go, they are confined to the description of his experiments. On the causes and laws of cylinder condensation, there is little in his Papers except some acute observations on special anomalies observed. Willans himself said that "he was unwilling to suggest any theory to account for the various results shown in these tables." But without a theory they remain as individual results for a particular engine, of a particular size and type, in particular conditions. Without a theory no one can use these results, say, to predetermine the steam consumption of any other engine of a different size, or in other conditions. What they do make clear is that the variation of steam consumption in different cases is exceedingly complex, so complex as sometimes to seem capricious.

Let me protest as strongly as possible, again with the reservation that I am stating my personal view, against the tendency to suppose that the great work of Willans' can be summed up in a so-called Willans' law, or that that law, handy as it may be for practical steam engineers, is more than a quite subordinate part of Willans' work. The Willans' law is nothing more than the empirical descriptive statement that the relation of total steam consumption and indicated or effective horse-power can be very approximately expressed by a linear equation, for the case of an unjacketed engine working with a fixed cut-off. Further, nothing is done in Willans' Papers to fix what is the linear equation for any given engine. So far as those Papers go, and until some kind of theory taking account of initial condensation is discovered, we can only find the relation of steam consumption and horse-power for any given engine by making two accurate trials of the engine itself. Willans' law leaves us in regard to any given engine in the same position as an astronomer with a new comet. When the comet has been observed for a sufficient period and some of its positions fixed, a probable orbit can be calculated. The straight line law leaves the steam consumption of a new engine as unknown as the elliptic law the orbit of a new comet.

Willans' law is being used, I am afraid, by many engineers with little discretion. I find engineers who assure me that they plot tests of automatic expansion engines in straight lines and that they find nothing wrong. But if Willans was right that the relation of steam consumption and horse-power for a throttled engine was linear, then it is demonstrable that the relation for an engine with varying expansion or varying speed must be of a more complex kind. I am driven to conclude that as to steam consumption with varying load engineers are content with rough approximations.

Willans himself says nothing whatever as to any possible rational basis for the Willans' law. He put it forward purely as the result of plotting his experiments. Later, Capt. Sankey showed that the total steam consumption of an engine working adiabatically with fixed ratio of expansion would also follow nearly but not exactly a straight line law if all clearance losses, radiation and exhaust waste and back-pressure loss were neglected. The adiabatic law is inconvenient in forming an equation for the relation of steam consumption and horse-power, and the actual expansion curve of

Digitized by Google

an engine is much more nearly an isothermal* than an adiabatic, because the steam receives heat from the cylinder wall. If we assume isothermal expansion (and really so far as the area of the diagram is concerned, it matters little what law of expansion is assumed) it is easy to find a formula for the total steam consumption of an engine working without clearance loss or exhaust waste. I have found such a formula and plotted the results both for a condensing and a non-condensing engine. The lines plotted are not exactly but very nearly straight lines. That carries us a certain way, but it is an enormous jump to assume without examination that the steam wastes in the engine, amounting to from 20 per cent. to 50 per cent. of the steam used and arising from causes of the most complex kind, depending on the volume of the clearance, the action of the cylinder wall, the loss of the toe of the diagram, the waste expansion between the cylinders, and other causes of loss, that this also can be expressed as a simple linear function of the horse-power.

Now in the first edition of his "Treatise on the Steam Engine," which appeared in 1878, Prof. Cotterill had seriously attacked the problem of cylinder condensation from the theoretical side. After Hirn, he was one of the first to recognise that the action of the cylinder wall was a superficial action, and further, what had not before been recognised, that it depends in some way on the admission surface reckoned per pound of steam used. He therefore studied the action of a plate of metal in the cylinder so thin that it would follow exactly the temperature changes of the steam. On comparing the results of this assumption with the data obtained in engine tests it appears that the temperature cycle in the cylinder wall cannot be, except in limiting cases, identical with temperature cycle of the steam, and this introduces a complication. Nevertheless, Prof. Cotterill found it possible to give a partly rational, partly empirical formula for cylinder condensation. The ratio of the water present to steam present at cut-off is

$$Y_1 = C \frac{\log_e r}{d \sqrt{N}},$$

where C is a constant for any given engine, and has only a limited range of values for engines of widely different sizes and proportions. But according to this formula for unjacketed simple engines the initial condensation has a fixed ratio to the steam present at cut-off. In the diagram lines for steam present at cut-off are given calculated in the manner already described. Above these has been set up the condensation by Cotterill's law, and the total steam consumption at various loads is then given by a line very nearly straight and closely agreeing with a Willans line.

But now if Cotterill's formula is trustworthy for determining the condensation in a throttled engine working at various pressures, there is no reason why with the same restrictions as before it should not apply to an automatic expansion engine. Another diagram shows first the curves of steam consumption, calculated by the formula mentioned before, which gives the steam present at cut-off, and above them curves of total steam consumption obtained by adding values of condensation calculated from Prof. Cotterill's formula.

The curves on the two diagrams agree well with Willans' results, and they differ from Willans' lines in being obtained entirely by calculation without experimenting on the engine. It would not be right to make too much of the coincidence, but I thought it would be interesting to show that theory and experiment converge. A good deal has yet to be done, but the discussion in Prof. Cotterill's treatise has done more than anything else to throw light on the conditions which promote or hinder cylinder condensation, and on the means useful in securing economy of working.

I should have liked, had time permitted, to mention another direction of experimental research which promises to be useful.

The purely dynamical actions in the engine like the thermal actions have proved too complex for any purely rational treatment. Here also it is necessary to check the results of theory step by step by reference to experiment. The total friction of engines has been determined by various methods and proves to be more nearly independent of the load than the earlier writers assumed. Hirn converted the beam of his engine into a flexion dynamometer which drew a diagram of the effective work of the engine, and some method of this kind might be revived with much advantage. Prof. Carpenter and Mr. Preston have attempted experiment on the friction of different parts of the engine, with the striking result that the crank-shaft bearings absorb nearly half the frictional work of the engine and the piston about one-fourth. Mr. Ransome has studied experimentally the action of governors, and lastly Prof. Dwelshauvers Dery has attempted a general experimental study of all the dynamical actions which affect the motion of the engine.

Since 1845 purely scientific men, scientific experimenters, and practical engineers have all been engaged in the study of the steam engine. I do not believe that any one of the three can claim all the credit for the improvement of the steam engine to the exclusion of either of the others.

What has been achieved is shown in the following table :—

Lowest Steam Consumption.

—	I.H.P.	Boiler pressure.	Piston speed.	Steam per I.H.P.-hour.
Simple—				
Sulzer	284	87	372	18·4
Corliss	137	62	...	17·5
Compound—				
Dujardin	548	90	570	13·46
Sulzer	247	85	493	13·35
Wheelock	590	160	612	12·84
Leavitt	643	135	371	12·16
Triple -				
Sulzer	615	141	516	11·85
Allis	574	120	203	11·68
Compound superheating—				
Schmidt	76	180	380	10·17

Representing, perhaps, rather the scientific than the practical interest, I do not think that the mathematical and physical researches of which I have tried to give an account have had no influence on the practical business of the engineer.

Of a few only of the more salient points in the history of the steam engine has it been possible in this lecture to give even a brief and imperfect account. The omissions I know are almost innumerable. I can only hope that no fault or omission of mine obscures the lesson that science and practice go hand in hand.

* [Prof. Unwin evidently means here :—*According to the law pv constant, the isothermal for a perfect gas.* The isothermal for steam is *p* constant.—Ed. *E.*]

THE SECOND LAW OF THERMODYNAMICS.*

BY PROF. OLIVER J. LODGE, F.R.S.

The science of thermodynamics is one that has been built up largely by engineers. Its pioneer was James Watt; its founder was Carnot; and of other illustrious names I need only mention Rankine, Clapeyron, Hirn, and James Thomson; while of non-engineers we are not likely to forget the names of Joule, Mayer, Clausius, and Kelvin. It is a very recent branch of science. Fifty years ago it had not been definitely proved that heat was a form of energy; in other words, its first and fundamental law was unknown. At that time a heat engine was thought to act on the same lines as a turbine or an electric motor, receiving heat, water, or electricity at one temperature, level, or potential, and discharging the same quantity at a lower temperature, level, or potential, its work being due solely to the drop in temperature without consumption of heat. Carnot struggled against the fallacy of this idea unsuccessfully (his work lay in the detection of the second law, not the first). Joule finally emancipated us from it, though not without a struggle on the part of the conservative upholders of the older and more simple doctrine.

We take it, then, as now established that heat is one of the forms of energy, and that when work is done by a thermal engine heat disappears, is actually consumed as heat, ceases to be heat, and reappears as some other form of energy. There is a real transformation of heat into work, using the term *work*, as is often popularly, though not quite accurately, done, as short for the longer term "mechanical energy." And heat is energy in a very concentrated form. The energy in a pint of boiling water, if it could be all utilised, amounts to more than half a million foot-pounds, and even if water were quite cold and on the point of freezing, it would still contain energy equal to 350,000 foot-pounds of work, or one-sixth of a horse-power-hour, in every pint. These numbers are only approximate, for lack of data; but, supposing the energy is anything approaching this, how comes it that we can utilise so little of it? How comes it that practically we can utilise none of it?

The second law of thermodynamics, as is well known, tells us the precise fact concerning possible utilisation; it asserts that if a working substance receives heat from a source T degrees above absolute zero of temperature, while the coldest of surrounding objects is t degrees above absolute zero, then the fraction $(T - t)/T$ of the whole heat received can be utilised under the most favourable possible circumstances, and the remainder, viz., t/T of the whole, must remain uselessly in the form of heat. This is a remarkable generalisation, since it is independent of the specific properties of any working substance; it asserts that the maximum possible efficiency of any heat engine whatever is limited by the range of temperature between which it works, being equal in fact to that range of temperature divided by the distance of

* Paper read before the Liverpool Engineering Society.

Digitized by Google

absolute zero, on the thermometric scale, below the highest temperature of the range; and it further asserts that this maximum possible efficiency is independent of all other things whatsoever.

But though the second law is scientifically precise and incontrovertible, it is hard at first to realise how and why it can be true that the temperature at which heat exists in bodies so entirely controls its availability or working power. The object of my Paper is to make this matter plain, by showing the heat energy is in this respect similar to all other forms of energy, and that the second law of thermodynamics is, after all, nothing more than enlightened common sense.

I will first adduce certain consequences of the law of efficiency which are frequently overlooked, or at any rate not emphasised so much as they might be, even if they are not occasionally disbelieved. (1) Since the higher the temperature of supply, and the lower the temperature of refrigeration, the higher is the attainable efficiency, it follows that all the heat should be supplied at the highest available temperature, whatever that may be, and the waste heat be withdrawn at the lowest available temperature. The highest temperature commonly available is that of a furnace, hence the heat should be supplied to the working substance in the cylinder at furnace temperature. This condition is roughly satisfied in internal combustion engines, though they have at present many other defects which almost compensate this great advantage, but in the steam engine it is not even attempted. Heat is supplied to the cylinder (by convection), from the boiler, and when discussing efficiency the boiler is treated as if that were the highest temperature available. The range of temperature practically attended to is the range between boiler and condenser, a range of some hundred or two degrees, while the immense drop of some thousand degrees between furnace and boiler is wholly ignored.

In contemplating boiler efficiency it is considered satisfactory if all the heat generated in the furnace is received by the boiler, and if the amount which goes up the chimney is only enough to maintain a draught. But this is ignoring two vital considerations: (1) that energy may be lost otherwise than as heat, (2) that the availability of heat energy depends upon temperature. The first of these considerations, indeed, is frequently attended to, and it will be readily admitted that it is not enough to utilise all the heat produced by the burning fuel, it is also necessary to ensure that all the fuel shall be burnt. Many furnaces and stoves are competent to distil their fuel up the chimney in an unburnt or partially burnt state, acting, in fact, like gas retorts. Deficiency of air and plentiful admixture with carbonic acid are the two prime causes of this waste—waste of fuel and of energy, though not of heat. The waste may occur although no *heat* passes up the chimney unutilised; the energy which escapes may be the chemical energy of unburnt gases not yet converted into heat. But it may be said that this is an obvious point, always attended to in firebox construction and in stoking. If so, very good; but there is another.

The heat is generated in the furnace at a high temperature, say 2,000deg. above absolute zero, or 1,500°F.; it is then communicated to the boiler at a much lower temperature, say 800deg. above absolute zero, or 300°F. What is the outcome of this 1,200deg. drop? All the heat may be economised, let us grant; we will suppose the furnace and flues and air inlets so constructed and arranged that all the fuel is thoroughly burnt, and that all the heat enters the boiler, the draught being maintained mechanically or in some other way, nothing but thoroughly burnt cool gases passing up the chimney; still there is a tremendous loss; $\frac{12}{20}$ths, or 60 per cent. of the whole *available* energy, is thrown away in the mere act of conduction through the walls and tubes of the firebox, and only $\frac{8}{20}$ths is transmitted to the working substance. With this saved 40 per cent. the engine now has to deal, and if it is a perfect engine, with its condenser at, say, 600deg. above absolute zero (110°F.), it can utilise one-quarter of it. That is to say, one-tenth of the energy developed by the combustion of the fuel is all that an absolutely perfect steam engine and boiler, working with boiler at 310°F. and condenser at 110°F., is able to develop in the form of gross or indicated work. Whereas, the theoretically possible proportion of heat energy, developed at 1,500°F. and utilised at 110°F., is 70 per cent. of the whole.

The higher the temperature at which heat can be imparted to a working substance, the greater the portion of that heat which is available for useful purposes.

It has been pointed out by Lord Kelvin, though at first it may sound a rather surprising fact, that even when the object to be gained is mere heat, when, for instance, the object is to warm a building, the lighting of a fire and direct supply of heat at a high temperature by combustion is not the most economical way. The heat needed to warm a building is low-temperature heat. The heat produced by a furnace is high-temperature heat. Hence even though every trace of heat is collected and applied to warming the building, the process is not economical, simply because it ignores and wastes the great drop of temperature which might have been utilised. It must always be freely admitted that economy is only one of many considerations, and that the directness and simplicity of obtaining by combustion the heat which is to be directly applied to warm a building may be sufficient to counterbalance all considerations of wastefulness. It is not practicable or wise always to push considerations of economy into practice; but that does not affect the principle, and if a principle is ignored it should be ignored knowingly, with full appreciation of what is being done, else sometimes it may happen that some old-fashioned process is continued through mere blind habit, when circumstances have so altered that a change is both permissible and desirable. In the present instance it is unlikely that the indication of theory need be put into practice at present or for some time to come; economy of fuel is not at present considered a vital matter—witness the ordinary open fire-place for warming and ventilating rooms—but, nevertheless, it may be perceived and admitted that by suitable mechanism more warmth could be imparted to a building by means of a furnace than ever was produced in that furnace.

In other words, a small quantity of heat at a high temperature may be so directed and utilised as to cause the supply of a much larger quantity of heat at a low temperature.

Suppose, for instance, it is required to warm a building by the combustion of gas. Let the gas be burned in a gas engine, and let the gas engine drive a reversed engine, a freezing machine, so as to receive heat from surrounding bodies, and deliver it up where required, raised 10deg. or 20deg. or 30deg. in temperature. If the arrangements were perfect an immense quantity of heat could be obtained from surrounding objects, raised the requisite few degrees and supplied to the building, by means of the small quantity developed in the gas engine by combustion at high temperature. One may illustrate the matter by an analogy. Suppose a reservoir a few feet above a lake were wanted to be filled with water, and suppose that on a neighbouring hill top a small supply of water could be had with a head of some hundreds of feet; it would be wasteful to try to fill the reservoir with the high-pressure water, even if there were enough of it. The right plan would be to utilise the high-pressure water to work a turbine and pumps, whereby the low-level water could be elevated the necessary few feet and supplied to the reservoir. If arrangements were perfect, the fall of a ton of water down 500ft. should elevate something less than 50 tons of water a height of 10ft.; so that the high-level water might be the means of indirectly filling a reservoir fifty times bigger than it could fill directly. I have spent some needless time over this illustration, because the moral is closely applicable to the case of heat. The difference between energy and available energy is a nice point, seldom fully appreciated; plenty of energy is useless, as useless for all working purposes as if it were non-existent.

As an example, we may take the case of compressed air. A pound and a quarter of atmospheric air occupies 100 gallons (or 16 cubic ft.), and if compressed to 20 atmospheres, say, by 680ft. head of water, or 300lb. to the square inch, it can be squeezed into 5 gallons by an expenditure of 48 foot-tons of work. But in the compressed state it has in itself no more thermal energy than it had in its expanded state, except in so far as it is heated by the compression, which heat will soon disappear on standing. At the same temperature the thermal energy of a given weight of air is constant—no matter what its pressure may be; in other words, if allowed to expand infinitely without receiving heat, it can do the same amount of work at whatever pressure it starts, provided it starts always at the same temperature. But though this is true for total intrinsic energy it is manifestly false for available energy. The available energy of the air under compression is considerable; while of the free air the available energy is none at all. And the reason is, that we have no practically available method of allowing infinite expansion—that is, expansion into a vacuum, except by expensively producing a vacuum beforehand. If we lived on the moon we might do it, but here we are submerged in a high-pressure atmosphere (a ton to the square foot) and nothing can expand automatically to a less pressure than that. Every cubic foot of ordinary air contains 2½ foot-tons of unavailable mechanical energy. Hence the work to be obtained from the compressed air must be got while it expands from its 300lb. pressure to 15lb. pressure (using round numbers), *i.e.*, while its pressure is falling in the ratio of 1:20. This can take place either slowly or else in two stages; if in two stages the volume might first change from 5 gallons to 42 5 gallons, during which the temperature falls 300°F., and work is done equal to 21 foot-tons; while in the second stage the air will warm itself up to its original temperature, doing nine foot-tons more work. Or the whole expansion may take place slowly at constant temperature; in which case 48 foot-tons of work can be got, the same as was needed for slow compression. But this energy is not really obtained from the air; it is extracted from surrounding objects by the expanding air. The energy of the air continues constant and unavailable so long as its temperature is not raised; all the work done in slowly compressing it went to warm surrounding objects, and when the air slowly expands this amount of energy is recovered. The compressed air constitutes a sort of machine for extracting this otherwise waste energy. Thus whereas both the high-pressure and

Digitized by Google

low-pressure air contain in themselves 40 foot-tons of unavailable energy, the high-pressure enables you to extract and utilise 48 foot-tons of otherwise useless heat energy under the most favourable conditions (or under the worst conditions it will part temporarily with 21 foot-tons of its own energy and then enable you to extract 9 more foot-tons, making 30 altogether obtainable under the worst conditions of expansion), whereas with the low-pressure air none of its energy at all is available.

The essence of all this is true of heat. A small body at a high temperature and a large body at a low temperature may contain equal quantities of heat, but the available portion of that heat will be quite different. Because in the one case there are other accessible bodies at a much lower temperature, in the other case all bodies are at the same temperature and no transfer is possible. High temperature heat is efficient because the other bodies into which it can flow are at so much lower a temperature—there is thus great activity of transfer. An analogy of a commercial kind could also be worked out. The purchasing power of a sovereign depends greatly on the need of sovereigns on the part of the person to whom it is going to be transferred. A lot of work can be got out of the transfer of a sovereign if it be transferred to a man whose need for it is very great. Thus we see that, whereas a small body at a high temperature above surrounding objects may contain as much heat or total energy as a large body at a low temperature, the heat will be available for use in one case and not available in the other. Whenever temperature drops, by reason of increased capacity of the body possessing it, the availability of its heat diminishes. And the reason is the same as in the case of the compressed air allowed to expand from a small vessel into one of large capacity—the practically available range of pressure or temperature has diminished.

The whole matter may be summarised thus. Energy is only useful when transferred, it is during transferences of energy that work is done, hence any condition that prevents or lessens the transferability of energy prevents or lessens the performance of work by means of it, *i.e.*, makes it more or less useless.

The mechanical energy of air at ordinary pressure is useless, because there is no way of letting it expand and transfer its energy to other bodies—say to a piston. The thermal energy of matter at average temperature is useless, because there is no way of passing it on, there is nothing to make the heat flow into other bodies. Whenever heat will transfer *itself*, as it will if bodies exist at different temperatures, then some work can be got out of the transfer; and the more transferable the heat—that is, the greater the difference of temperature—the more work can be got. *The transferable portion of heat is to the whole heat as the available difference of temperature is to the whole temperature above absolute zero. Hence the efficiency of transfer, which means the ratio of the transferable to the total heat, is equal to the ratio of the available difference of temperature to the maximum absolute temperature.* And this is the second law of thermodynamics.

The following pressure-volume diagram illustrates the second law of thermodynamics in the simplest possible way, if the two curved lines are any pair of adiabatics, corresponding to the range of entropy through which it is convenient to take the working substance, and if the two crossing lines are isothermals as labelled. The areas then represent the proportion which the useful energy bears to the whole; and show clearly why a Carnot cycle between the highest and lowest available temperatures is the best possible cycle for economy.

I would especially call attention to Fig. 1, as summarising compactly all the chief general doctrines about heat engines. Though, to complete it, it should be understood that a set of isothermals crossing the adiabatics constitute the rungs of a temperature ladder, the steps corresponding to equal degrees if the areas partitioned off are equal, and the bottom rung corresponding to absolute zero.

To sum up this portion of our subject:—A working substance above average pressure has some available mechanical energy. A working substance below average temperature has some available thermal energy. But a working substance at average pressure and temperature is in equilibrium with surrounding bodies, and whatever energy it possesses is then useless.

By the use of a refrigerator and an air pump it may be possible to allow expansion into a vacuum, and in that case to get much more energy of a substance used; in fact, with a perfect air pump the *whole* of the energy of a body could be utilised, because expansion could go on indefinitely; but then the work done in maintaining the vacuum must be taken into account, and it very soon attains an amount as great as, or greater than, what could be gained. This is sometimes apparently forgotten in engine trials. Allowance is not always made for the work required in pumping. That a gas engine has to do pumping, and that its cycle is, therefore, a double one, everybody knows. But that a steam-engine cycle is also essentially a double one is often ignored. Yet it is true. There is both the air pump and the feed pump to be subtracted. It may be that these are worked by separate engines, but that does not prevent the need for subtracting the work of these auxiliary engines from the output of the main engine, in reckoning its actual efficiency. It would otherwise be possible to propel the main engine solely by aid of the auxiliary engine working its air pump, and thus its efficiency might be made obviously artificial and absurd. The working substance must always be taken round a complete cycle, and its consideration must not be abandoned till its cycle is complete, else the engine is not a heat engine alone, but is consuming substance as well, like a voltaic battery or a horse or a gunpowder engine. These chemical machines may have far higher efficiency than steam engines; they are not controlled by considerations of temperature. The cycle of a steam engine is a double one; the working substance must be put back into the boiler before the series of operations is complete.

I have now displayed the reason why a heat engine is so entirely controlled by considerations of temperature, and why the maximum efficiency is $T-t/T$, where T is the highest and t the lowest temperature available. It is because (1) temperature determines transfer of heat, and heat will only flow "downhill"; (2) because every kind of energy is only useful for working purposes when automatically transferred.

Observe that in the fact that it will only flow "downhill" as regards temperature, *i.e.*, from hot to cold, conduction of heat differs from other processes which are in many respects analogous.

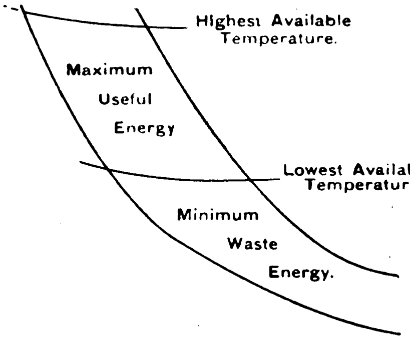

FIG. .

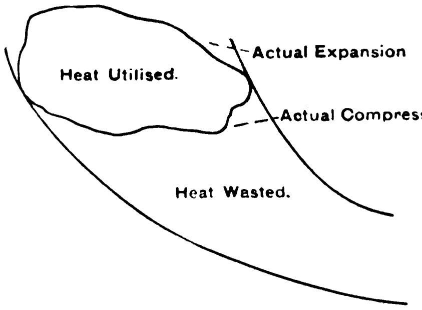

FIG. 2.

Thus, although water will not flow uphill *continually*, unless it is pumped, yet for a time it will flow uphill with perfect ease. It happens for nearly three hours in a tidal channel, when the momentum of the incoming water carries it up into regions of greater elevation, against opposing forces; which ultimately, however, drive it back again. An air stream, again, may flow from a low-pressure reservoir into a high-pressure reservoir for a short time, if it is started with sufficient impetus or momentum. So also a current of electricity can rush from feebly-charged into a highly-charged body, or from a conductor at negative potential into one of positive potential, by reason of what is called its electromagnetic momentum. It is this capacity for travelling against opposing forces which constitutes the property of *inertia*, and which causes all manner of oscillation. In fact, the simplest of all such cases is the bob of a pendulum, which at every alternate quarter-swing travels up against the force of gravity, until stopped and brought backed by the opposing force. But none of this is possible with heat. Heat cannot flow, even momentarily, from cold to hot. It has nothing corresponding to inertia or momentum. It flows only and solely when urged forward by a higher temperature behind it and a lower temperature in front of it. This is true even for radiation, in a sense, and no burning-glass focus can be hotter than the sun.

It remains to ask *why* heat is only thus transferable; whether it is a definite and unalterable fact, or whether it depends on our present ignorance, that heat can never be got to transfer itself automatically between two bodies at the same temperature. We know that heat is molecular energy, and some forms of molecular energy have no connection with temperature, and can be utilised

Digitized by Google

readily enough, although quite cold. As instance, I adduce winds and currents. But in such cases the available motion of the molecules is all in one direction—it has a certain regularity about it—it may be directed and controlled. The molecular motion which constitutes *heat* is not like that—it is perfectly random and irregular—our only way of utilising it is by the bombardment or pressure which the molecules exert upon a surface which they hit by chance in the course of their irregular and uncontrollable motions. Osborne Reynolds puts the matter thus: Here is a chain attached to a weight, and the problem is to raise the weight by means of the chain. Simple enough if we know how to give the chain a vertical pull, but, in the case of air or steam or other working substance beneath a piston, that is just what we cannot do. We cannot make the molecules all move upwards and raise the piston, we can only agitate and knock them about irregularly—a process which we call "heating" the gas. The analogue of the process is shaking the chain. Suppose we can only shake the top of the chain irregularly, waves and disturbances will travel down it, it will get into irregular form, and the weight at the lower end will rise. Our object has been accomplished, but in a wasteful and indirect sort of manner. Precisely so is it when we attempt to utilise the irregular molecular agitation which we call heat. Having raised one weight by shaking the chain, another weight can be raised, and so work can be done perpetually, *provided* that we detach the first weight at its higher level and then let the motion die out of the chain; that is, provided we cool the working substance back to its original condition and so complete the cycle. The only difference between the initial and final conditions lies not in the working substance but in the raised weight, *i.e.*, in the external work done. The substance has been brought back to its old condition but an area has been surrounded on its indicator-diagram.

The necessity for alternately heating and cooling the working substance, simply because it cannot constantly expand for ever, is of somewhat the same nature as the necessity for brushes or sliding contacts in a dynamo, whereby the current which was excited in each segment is periodically stopped and reversed. The area of a circuit cannot increase constantly for ever, without this device.

It will be observed then that the second law of thermodynamics relates to the utilisation of heat energy *as heat*, *i.e.*, as perfectly irregular and uncontrollable molecular motion. If by any means molecular motion could be taken under control it would cease to be heat—the second law of thermodynamics would not apply to it—and a much greater proportion of its energy might be available; availability would, in fact, then not depend upon temperature, which is a term appropriate to the consideration of heat as heat; "temperature" would cease to be a serviceable term if we were dealing with visible and controllable molecular motion. It is, however, conceivably possible some day to regard this motion otherwise than as heat. We have not learnt how thus to deal with it yet, but we already know many ways of dealing with special varieties of molecular energy otherwise than as heat. For instance, the chemical molecular energy employed in the voltaic battery, is much more controllable than if it were first converted into heat. Again, the leaves of trees do not turn solar rays into heat, but they utilise the solar energy direct, in order to elaborate their sap. Animals again do not turn their food energy into heat, but they utilise it direct. They are not heat engines. If they were, they would be miserably inefficient, because of their low temperature; but they are not, they are chemical engines, analogous to the voltaic battery, and are marvellously efficient; so much so that the attempt is sometimes made to turn them into perpetual motion machines, by beating more work out of them than corresponds to the combustion energy of the hay which is put in. There is some heat produced during muscular action, as a waste product, it is true, but it is only a small fraction of the whole energy utilised.* So hereafter it may come to be possible to use even the random energy of heat in a direct manner, simply by directing and controlling the molecules so that their motion is no longer perfectly irregular, so that in fact it ceases to be mere heat and becomes a higher form of energy, transferable on lines other than those controlled by temperature. Already it is suspected that certain bacteria and microscopic forms of life have the power to do this; and, if so, for them the second law of thermodynamics does not exist. It is indeed no ultimate and final law. It will always be true of heat engines working by means of expansion, but it will not be universally true when any portion of heat can be intelligently treated as definite molecular energy.

Practical Outcome.

Since the two laws of thermodynamics assert (1) that when work is done by a working substance in a heat engine a portion of its heat is consumed and utilised, and (2) that the portion thus utilised is immediately dependent on the temperature of the working substance; it follows that a substance suitable for use in a heat engine must have two qualities. (1) It must have a great capacity for heat, so as to store and carry with it a great quantity of energy. (2) It must be able to stand a high temperature.

Air and permanent gases satisfy the second condition admirably, but not the first. There is no limit to the temperature to which they may be raised, but their capacity for heat is small. In order, therefore, to get very much work out of a hot-air engine it must be unwieldy in size, or else it must be worked at a bursting pressure such as is suitable in cannon. You cannot get more energy out of your cylinder than the working substance conveys in, and it takes a great deal of hot air to convey much energy.

Saturated vapour has a far more concentrated capacity. When a liquid passes into the vaporous state, an immense quantity of heat is stowed away, even without considering a rise of temperature; in the case of water boiling as much heat as would raise the water about 900 degrees, as much as would raise an equal weight of air 3,600 degrees, is stowed away in the steam without making it any hotter. This is the most valuable property of steam, that it is able to contain such an immense quantity of energy in a small mass of material. Hence, as Fitzgerald has pointed out, steam engines can be moderate in size and yet powerful.

But the defect of steam is that its boiling point is so low, it will not stand a high temperature without an altogether exorbitant and impracticable pressure. What is wanted is a substance that shall be equally or more expansible, but which can be made much hotter while its pressure is still within moderate bounds. Substances with higher boiling points naturally suggest themselves;* mercury, say, or perhaps other moderately fusible metals. A substance which boils at a red heat is the kind of thing wanted, but then metals mostly have a rather low latent heat of vaporisation, and that is against them; they would not have a very great heat capacity. Still, a substance might be found that could stand a suitable temperature when at high-pressure boiling; and if, when its vapour was condensed at low pressure, its heat were not exhausted, the condensed but still hot substance might be used to boil another liquid, say, water or ether or SO_2 or something with lower boiling point, which ultimately would condense a very low temperature.

The suggestion of a number of engines in series, the hottest a combustion engine, and the coldest a vapour engine, is no new one, it was made by Carnot. Of course, it may happen that the same substance in different states might serve; for instance, steam itself need not be used in a saturated state, it may be superheated without limit, even till it is dissociated, and used so, being only finally employed in its ordinary saturated condition. But then the other objection arises, that in this gaseous state it has so small a heat capacity; most of the heat was passed into it when it boiled and became vapour, and that was at a comparatively low temperature; the amount of energy it can receive during superheating is not very great. The advantage of superheating steam in practice is immense, and the reason of the gain is perfectly known, but it is not much owing to the extra energy thereby imparted; it is due to the fact that condensation during expansive working can thereby be prevented. Saturated steam is an unfortunate substance in this respect, it cannot expand adiabatically without condensing; hence during the expansive part of the stroke the cylinder gets partly full of water. Substances are known which have not this defect: Chloroform vapour is one such substance. It behaves oppositely to steam, it condenses when compressed and dries when allowed to expand,† hence chloroform vapour would in that one respect be better than steam. But the high latent heat of steam is an advantage not to be readily replaced, and it is probably best to use steam, but to counteract the tendency to condensation by excessive and continual superheating. Only I would jacket everything—the cylinder and the connecting pipes and the reservoir—not with steam but with furnace heat—with the waste gases of the furnace—so as to superheat strongly and economically. At every passage from one cylinder to another there should be jacketing—even the low-pressure cylinder should be jacketed too. No condensation is wanted or should be permitted till the actual condenser is reached.

But no minor improvements will overcome the one radical defect of every mere steam engine, that the high temperature of the furnace is ignored and unutilised; the great drop of temperature between furnace and boiler is thrown away. Of course it is used for transmitting the heat quickly through the walls of the firebox, but one reason why this transmission of heat is so difficult is because those walls are so cool. They interfere with combustion, and accordingly flame cannot come into contact with them. The heating of a boiler is done mainly by radiation through a thin stagnant gaseous film intervening between flame and boiler tube. And gases are shocking bad radiators—smoke is better—and this is the reason why bad stoking and smoky chimneys sometimes unfor-

* Since this Paper was read, a great physiologist, Prof. Engelmann, of Utrecht, in his Croonian lecture before the Royal Society (March, 1895), maintains the opposite doctrine; being of opinion that heat in muscles is *not* a waste product but is the efficient cause of their contraction. I adhere distinctly at present, to the view expressed in the text: but I state the opposition, that no student may be misled into considering it as finally accepted truth.

* *See* a letter by Lord Rayleigh in *Nature* 1893 or 1894.

† This was predicted theoretically by Clausius.

tunately answer better than complete and clean combustion. If the boiler could be heated by direct flame contact this condition of things would be entirely altered. And the only way to permit flame to come into contact with the boiler surfaces is to permit them to be red or white hot—hot enough not to interfere with combustion. At present they interfere with it in the same way as do meshes of a safety lamp. Everything, therefore, points to the advantage of a high-temperature working substance; with such a substance no excessive gradient of temperature would be needed, heat could flow into it from the furnace easily. Either this plan, or some form of internal combustion engine where no conduction of heat is needed, seems to be the direction in which theory points.

The ingenuity of engineers has been successfully applied to the minor economies of the steam engine, so that from boiler to condenser and back again it is a beautiful machine, within the limits imposed by the laws of nature. Thermodynamics, however, points to the possibility of an economy, not of some 5 or 6 per cent., which is almost all the present difference between the best steam engine and the worst, but to a revolutionary change of 50 or 60 per cent., no drop of temperature from furnace to every-day temperature being permitted without delivering up its due equivalent of motive power.

THIRD REPORT OF THE ROYAL COMMISSION ON ELECTRICAL COMMUNICATION WITH LIGHT-HOUSES AND LIGHT-VESSELS.

[Abstract.]

In our first report,* made in December, 1892, we recommended that electrical communication should be established with five light-vessels, one pile lighthouse, 19 shore lighthouses, and four lighthouses on islands or isolated rocks. When, in March, 1894, we issued our second report,† sufficient progress had not, in our opinion, been made to justify us in adding to the list, and we confined our recommendations to the connection of further shore lighthouses, with 19 more of which we urged that electrical communication should be established. Effect has now been given to all the recommendations made in the two reports which we have already issued, except in the case of the "Scarweather" lightship and Caldy and Fastnet lighthouses, and we assume that the connection of these stations will shortly be taken in hand. We therefore submit a further list of stations which we recommend should be connected with the telegraphic system of the United Kingdom as soon as possible.

Before we deal with this list we desire to make a few observations on the subject of the connections which have already been effected, and more especially on the connections with the lightships.

Methods of Electrical Communication with Light-Vessels.

The system which has been adopted in establishing electrical communication with the four light-vessels which are at present connected with the mainland is, with certain modifications, that known as the "Sunk" system, under which communication was maintained with the "Sunk" lightship from November 12, 1886, to January 1, 1889, with only two interruptions. The ship is moored by two or more chain cables attached to mushroom anchors and shackled the lower part of a patent swivel, to the upper end of which are shackled to the vessel's two bridle chains. The electric cable on its way from the shore passes through the centre of the swivel and, entering the bow of the ship between the knightheads, is coiled on a drum fitted to a revolving frame placed between decks, by means of which turns made in the cable when the lightship swings round with the change of tide can be taken out. This system permits of the free use of the telephone, which in our opinion is an important advantage. Since we issued our second report we have considered some further inventions for establishing electrical communication with light-vessels, but we still consider that the "Sunk" is the best system of continuous connection which has yet been brought to our notice. At the same time we think it is desirable that a trial should be given to a system of communication by induction, in order that we may be able to judge, before we issue our final report, whether such a system can be used under conditions (*e.g.*, in deep water and over a rough bottom) which render the establishment of electrical communication with light-vessels by means of the "Sunk" system a matter of very great difficulty.

Working of the Cables.

Electrical communication was established with the "Kentish Knock" light-vessel on March 14, 1894, and between that date and December 31, 1894, communication was interrupted on four occasions. Two, at least, of these interruptions appear to have been caused by want of experience on board in the management of the electric cable, and we anticipate that interruptions arising from this cause will tend to become fewer as time goes on. The "Goodwin" (North Sand Head) light-vessel was connected with the mainland on March 24, 1894, and between that date and December 31, 1894, communication was interrupted on two occasions. We visited this vessel on August 4th last, and it was then apparent to us that the veering (electric) cable would not much longer stand the wear caused by the strong tidal action. The strength of the tide at this place is sufficient to sweep the bottom clean, and consequently the veering (electric) cable is constantly being threshed upon the hard bed of the sea. The anticipations which we formed on the occasion of our visit to the lightship were realised on August 26th, when the veering (electric) cable had to be taken up for renewal. Communication was restored the same day. Communication was interrupted for the second time on September 3rd, and was restored on September 15th. The second interruption was caused by one of the vessel's mooring chains giving way, and cannot, therefore, be attributed to any defect in the system of electrical communication which has been adopted. The "Hasborough" light-vessel was connected on October 2, 1894, and the "Shipwash" light-vessel on November 17, 1894. No interruption in the communication established with these vessels had occurred up to December 31, 1894, although some defects had from time to time become apparent.

The record of the interruptions in the connections with the "Kentish Knock" and "Goodwin" light-vessels does not, it will be observed, compare favourably with that of the interruptions in the communication established with the "Sunk" light-vessel during the period from November, 1886, to January, 1889, to which reference has been made, but we consider that an explanation of this can be found in the fact that by November, 1886, the crew of the "Sunk" had acquired considerable experience in the management of the electric gear, as their ship was first connected in December, 1884. This experience was only obtained after several interruptions had occurred in the working of the electric cable, and we find that the number of occasions upon which communication with the "Sunk" was interrupted during the first nine months is greater than in the cases of the "Kentish Knock" and "Goodwin" lightships during the like period. We anticipate, therefore, as we have previously mentioned, that as the crews of the light-vessels become more experienced in the management of the electric cables, and the other apparatus by which the connections are effected, the interruptions will tend to become fewer.

No difficulty has arisen in regard to the connection with the Gunfleet pile lighthouse, which was effected on October 2, 1893, or to the connection with the Tuskar lighthouse, which was completed on September 10, 1894. As regards the cable to the Lundy lighthouse, the extension to which dates from July 18, 1893, a new shore end had to be inserted in September 1894, the original cable having become chafed at the part where it was landed on the island.

Use Made of the Connections.

We have obtained from the general lighthouse authorities returns showing the occasions upon which use, for the purpose of giving information regarding vessels in distress, has been made of the electrical communication now established on our recommendation with light vessels and lighthouses round the coasts of the United Kingdom.

From these returns (contained in an Appendix to the Report) it is found that, up to the close of the year 1894, use, for the purpose stated, had been made of the electrical communication with the "Kentish Knock" light-vessel (connected March 14, 1894) on six occasions; "Goodwin" (North Sand Head light-vessel, connected March 24, 1894) on nine occasions; "Hasborough" light-vessel (connected October 2, 1894) on two occasions; "Shipwash" light-vessel (connected November 17, 1894) on one occasion; and Gunfleet pile lighthouse (connected October 2, 1893) on 19 occasions. No use for life-saving purposes had been made of the cables to the Lundy lighthouse (connected July 18, 1893) and the Tuskar lighthouse (connected September 10, 1894).

As regards shore lighthouses, use had been made of the electrical communication for such purposes with the Start Point on four occasions, Needles, three; South Stack, two; Nash, two; Bull Point, one; Point of Ayre, one; Douglas Head, one; and Hook Point, one.

For many years past there has been in use on board light-vessels a system of signalling to the shore and to passing ships whenever any vessel has been seen to be standing into danger or to be in want of assistance, and this system is being, and will be, continued by the lighthouse authorities concurrently with the new system of electrical communication.

We are satisfied that the telephonic connections which have been established with lighthouses and light-vessels have added in a very important degree to the effectiveness of the machinery which exists on our coasts for the purpose of rendering aid to vessels in distress and of saving their crews from the perils of the sea, and we consider that a perusal of the extracts from the logs of the "Kentish Knock" and "Goodwin" lightships and the Gunfleet lighthouse, which are given in Appendix A, will show very forcibly the advantage which electrical communication possesses over communication by ordinary signals in affording full details regarding endangered ships. It enables the lighthouse keepers and the crews of the light-vessels to give, in all weathers, precise particulars, not only of the position of ships in distress, but also of the nature and amount of assistance required to save them or their crews, and to prevent a lifeboat being sent out when only a tug or the rocket apparatus can be of any use, while, in the absence of such communication, details of this nature can only be given by means of visual and sound signals, which do not afford such exact information, and which are distinguishable even under favourable circumstances at a very limited distance.

From the records contained in Appendix A it will be seen that the Kentish Knock" and "Hasborough" light-vessels and the Start lighthouse had occasion to summon tugs, while the Nash lighthouses were enabled to send for the rocket apparatus, by means of which three lives were saved.

Recommendations.

I. We recommend that the "Formby" light-vessel be connected with the mainland as soon as possible by the system known as the "Sunk" system, which we have already explained. The "Formby" light-vessel is the middle one of the three lightships in Liverpool Bay which mark the Queen's Channel, the main entrance to the Mersey, and commands a good view over the places where a large number of casualties occur, viz., the

* See *The Electrician*, Vol. XXX., p. 396, February 3, 1893.
† See *The Electrician*, Vol. XXXII., p. 728, April 27, 1894.

Digitized by Google

west points of Taylor's Bank and Burbo Bank. The loss of life in the neighbourhood of the "Formby" lightship during the past few years has been heavy. The light-vessel lies in six fathoms of water over a bottom of sand and mud, and it is anticipated that the connection will not be a difficult one to effect and maintain. She is 3½ (nautical) miles distant from the land at Formby Point.

II. We recommend that the Maplin pile lighthouse be connected with the mainland. This lighthouse is situated on the outer edge of the Maplin sand, which runs for several miles along the coast of Essex from Shoeburyness northwards. It is distant from the nearest coast about five miles, &c. It is 15 (nautical) miles south-west of the Gunfleet pile lighthouse, which is already connected, and these two lighthouses command a good view of most of the inner shoals to the north of the entrance to the Thames, upon which a very considerable number of casualties to vessels have occurred during recent years. The bottom between the lighthouse and the shore being of sand and mud is favourable for a cable.

III. We recommend that the Smalls lighthouse be connected with the mainland by means of a continuous cable. The Smalls lighthouse stands on a rock 15 (nautical) miles west of the coast of Wales. It guards the Hats and Barrels Rocks, past which strong tidal currents run, and commands a view over the south-east entrance to St. George's Channel, the south-west entrance to which is commanded by the Tuskar lighthouse, which has already been connected. There is a large passing trade, and casualties to vessels involving loss of life have occurred near the lighthouse of late years.

The desirability of connecting the Eddystone lighthouse with the mainland has been strongly urged on commercial and other grounds, and the recommendation to this effect of the Court of Inquiry into the stranding of the "Dunottar Castle" in August last has been brought to our notice. The Eddystone occupies a very important position as a guiding mark for ships navigating the English Channel, but there are no outlying shoals or rocks beyond a distance of 400 yards from the lighthouse, and only two strandings on these rocks, including that of the "Dunottar Castle," have been reported during the last 12 years, no lives being lost in either case. In the case of the "Dunottar Castle," under different conditions of tide and weather, there might have been heavy loss of life which electrical communication with the shore might have averted, but the chances of casulties occurring on the Eddystone being small the terms of the Royal warrant by which we were appointed appear to preclude our recommending its connection, the cost of which is estimated at about £2,600.

Since the issue of our last report the telegraph cable between Tory Island and the coast of Donegal has been taken over from the Committee of Lloyds by the Government.

IV. We recommend that electrical communication by means of aerial wires be established without delay with the following shore lighthosues, viz., Little Ross, Bidston, and Llanddwyn.

We consider that the value of the warning conveyed to passing vessels by the display of storm signals on the occasion of the approach of heavy gales can scarcely be over-estimated, and we recommend that the lighthouses on the most prominent points of the coasts of the United Kingdom, with which electrical communication exists, should be made storm-warning stations. [Twenty-five lighthouses selected.]

Schedule of Recommendations.

1. Electrical communication to be established with the following light stations :—

(*a.*) **Light-Vessel**—

Name.	To be connected by telephone with	Cost of cable and laying.	Cost of land line.	Total cost.
Formby...	Crosby Lighthouse	£1,675	£55	£1,730

(*b.*) **Pile Lighthouse**—

Name.	To be connected by telephone with	Cost of cable and laying.	Cost of land line.	Total cost.
Maplin ...	Southend P. O.	1,505	470	1,975

(*c.*) **Rock Lighthouse**—

Name.	To be connected by telephone with	Cost of cable and laying.	Cost of land line.	Total cost.
Smalls....	Littlehaven C. G. S. ...	4,380	40	4,420 *
	Littlehaven C. G. S. to Pembroke Dock	—	180	180
			Total	£4,600

(*d.*) **Shore Lighthouses**—

Name.	To be connected by telephone with	Estimated cost (approximate).	Remarks.
Little Ross...	Borgue, P. O............	£200	The connection of this lighthouse has already been effected.
Bidston	New Brighton Ferry Stage	80	
Llanddwyn...	Newborough P. O. ...	—	
Total.......................		£280	

The total approximate cost of giving effect to the above recommendations is therefore £8,585.

The estimated annual cost (approximate) of providing for the display of storm-warning signals at the 25 lighthouses is £25.

Concluding Remarks.—Our tours of inspection during last summer were confined to a visit to the "Goodwin" (North Sand Head) lightship, and to the lighthouses and light-vessels near Liverpool. From Liverpool we proceeded along the north coast of Wales, and inspected the Great Ormes Head, Lynus, and Skerries lighthouses. It has been represented to us that we should visit Denmark, and inspect the system of electrical communication with island lighthouses, and between shore lighthouses, signal stations, and life-saving stations, which exists in that country. We regard it as highly desirable that before we conclude our inquiry we should investigate the system existing in a country where electrical communication with lighthouses has been established for some years, in order that we may be able to take advantage of any arrangements which experience may have suggested, and as Denmark seems to us to be the country in which we are likely to learn most, and the permission of the Danish Government has been granted, we propose to proceed thither during the ensuing summer and inquire into the working of the system in that country. We shall then, we trust, be in a position to prepare the way for our final report. (Signed) Mount-Edgcumbe (Chairman), Henry Lyle Mulholland, Edward Birkbeck, F. L. M'Clintock, G. S. Nares, J. C. Lamb, W. H. Preece, John A. Kempe, R. Munro-Ferguson, Ernest G. Moggridge (Secretary). Dated April 26, 1895.

* This estimate provides for looping in Littlehaven C. G. S. on the Pembroke Dock—St. Ann's Head Admiralty circuit.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, May 17th.

Institution of Electrical Engineers.

8 p.m. Students' Meeting in the Library of the Institution, 28, Victoria-street, S.W. Paper to be read: "Aluminium," by Gerald C. Allingham.

TUESDAY, May 21st.

Institution of Civil Engineers.

8 p.m. Ordinary Meeting in the temporary offices, 9, Great George-street.

WEDNESDAY, May 22nd.

Society of Arts.

8 p.m. Ordinary Meeting. The following Paper will be read: "The Dressing and Metallurgical Treatment of Nickel Ores," by A. G. Charleton.

THURSDAY, May 23rd.

London Chamber of Commerce.

2:30 p.m. Special Meeting in the Hall of the Carpenters' Company, London Wall, when Mr. W. H. Preece, F.R.S., will deliver an Address on "Telegraphy by Induction."

Royal Institution.

3 p.m. Afternoon Lecture. "The Instruments and Methods of Spectroscopic Astronomy," by William Huggins, F.R.S.

Institution of Electrical Engineers.

8 p.m. Meeting at the Society of Arts, John-street, Adelphi. Continuation of Discussion of Mr. Mark S. Robinson's Paper: "On the Recent Development of the Single-Acting High-Speed Engine for Central-Station Work."

FRIDAY, May 24th.

Physical Society.

5 p.m. Meeting at Burlington House. Papers to be read: (1) "On Mixtures of Ethane and Nitrous Oxide," by Dr. Kuenen; (2) "The Measurement of Cyclically Varying Temperatures," by H. F. W. Burstall.

Royal Institution.

9 p.m. Friday Evening Discourse: "The Absolute Measurement of Electrical Resistance," by Prof. J. Viriamu Jones, F.R.S.

Electricity in Hungarian Mines.—An electric railway has been laid down at the Mizserfacsibaj mines in Hungary. It connects the main shaft with the loading place, a distance of about 1¼ miles. The gauge of the line is 2ft., and there are gradients of from 2 to 6·5 per cent. The locomotive, of 6 h.p. capacity and 20 tons weight, is only 3½ft. wide and 4½ft. high. It draws 18 to 20 trucks at a speed of about 10 miles an hour. Double-wire overhead conductors are used, which run in the mines about 6½ft. above the rails, and in the open nearly 10ft. The working pressure is 300 volts, the 40-h.p. generator at the general engine house, at one end of the railway, also supplies current to a winding machine, a pump and a cutter. At the Ludovikaschacht a transmission of power plant has also been installed. A 100-h.p. generator, driven by a turbine, supplies current to a 30-h.p. hoist 775 yards away, and a 14-h.p. rock-drill, which works some 1,200 feet below ground. The spare power is used for lighting at the Unterfermezely mine; a blower and a ventilator are driven electrically. This latter requires a current of 40 amperes at 550 volts, and is about 1·6 miles from the generating station. The Bleiberg Mining Union of Bleiberg proposes to establish a plant for the utilisation of available water power to the extent of about 350 h.p. The plant will be on the multiphase system, and the electrical energy will be transmitted to the Bleiberg mining district, a distance of about 5½ miles, there to be used for miscellaneous power purposes.

The Electrician.

(The Oldest Electrical Journal, 1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny.
Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	YEAR.	HALF-YEAR.	QUARTER.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* **4** *p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE By Dr J. A. FLEMING.
- VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
- VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d. post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s 6d.. post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s 6d. post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation.*

SPECIAL NOTICE.

Owing to the growth of the electrical and allied industries the demands for space in "THE ELECTRICIAN" are, for the greater part of the year, so pressing that a permanent increase in the size of the journal has become necessary. To meet the increased cost involved by this step, and by other improvements, such as heavier paper and more numerous illustrations, the price of "THE ELECTRICIAN" has from May 3rd been advanced to 6d. Hitherto this sum has been charged when the number has contained a Supplement, and, as the industries grow, these may be more frequently necessary; but the practice of charging extra for Supplement numbers as issued will be discontinued.

The Subscription to "THE ELECTRICIAN," commencing with Vol. XXXV. (May 3, 1895), is as follows:-

	YEAR.	HALF-YEAR.	QUARTER.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

NOW READY.—Vol. XXXIV. of "THE ELECTRICIAN," bound in strong cloth. Price 12s. 6d., post free 13s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

MUNICIPALITIES AND THEIR ELECTRICAL ENGINEERS.

It is just about a year ago that we had occasion to make a few observations on the subject of the salaries which most municipalities thought it advisable to offer to engineers, upon whose shoulders they proposed to rest the burden of carrying on to a successful issue such important and exceedingly novel enterprises as municipal electric lighting central stations. As we then pointed out, even granting that the iron law of supply and demand could be rigidly applied in fixing such salaries, which we deny, the actual supply of competent men is short of the actual demand; although, of course, if it be assumed that every applicant for a post is capable of filling it, one must admit that the conditions are reversed. Our suggested remedy of a year ago—and nothing has occurred in the interval to cause us to alter our opinion—was that the real relation of supply to demand could be easily ascertained if electric lighting committees and their expert advisers, instead of attempting the invidious if not impossible task of drawing up an exact definition of the term "electrical engineer," would agree to insist on a minimum standard of qualification; say three years in shops and three in a central station or similar position. The law of supply and demand does not. therefore, afford a clue to the low rate of remuneration prevailing, provided

Digitized by Google

genuine competency be taken into account. Neither do many other politico-economic considerations, which are usually urged whenever the cry of low wages is raised, throw much light on the matter. To be badgered and bothered by fussy committee men, to have one's qualifications and character, merits and demerits, publicly and not too delicately discussed every time a rise of salary is humbly asked for or a breakdown occurs, does not tend to bring the function of municipal electrical engineer within the category of "agreeable employments." And, again, when one remembers the years which have to be, or should be, spent in going through the examination and laboratory mill at technical colleges, in picking up practical wrinkles in the shops, in working for nothing "to gain experience," it can scarcely be argued that it is cheap and easy to become a well-qualified electrical engineer. Apart from the large apparent supply to which we have alluded, the *fons et origo malorum* is, perhaps, to be found in the fact that electrical engineering has for obvious reasons attracted an unduly large proportion of men of independent means. Now we are assured by the straitest of political economists—and the question we are discussing would seem to be a case in point—that when an occupation is carried on chiefly by persons who derive a portion of their subsistence from other sources, its remuneration may be lower almost to any extent than the wages of other very similar employments. "You mustn't think I am entirely dependent on what I earn," we once heard a rising electrical light remark, little thinking how the very prevalence of that condition in the electrical engineering profession was mainly responsible for the low rate of remuneration so much complained of. If electrical engineers were more frequently entirely dependent upon what they earned they simply could not accept the salaries they now so often take, to the prejudice of their less fortunate fellows. The purely nominal wage so widely met with among the devotees of applied electricity in general, and municipal electrical engineers in particular, may also be partly traced to the absence of any long-established custom. With use and wont to guide them, even the narrowest visioned, most penny-wise-and-pound-foolish "economaniacs" might be trusted not to work much harm. But beside electrical engineering, even such recently-born professions as modern civil or mechanical engineering appear positively senile; whilst the callings of the lawyer and the doctor are covered with a genuine paleozoic crust of custom and etiquette. The narrowest economic considerations thus have their full effect when it comes to fixing the pay of the unfortunate municipal electrical engineer. What wonder that, with such a large apparent supply of competent men and with such readiness to accept ridiculously small salaries, stipends of £150 or £200 a year are deemed sufficient ?

Without, however, entering the debatable region of ethics, it is quite possible to argue, on the ground of bare expediency, that the low salaries which until lately were universal, and still remain the rule, are a mistake. Men tantalised by such doles naturally become mere birds of passage; ready to take flight to fresh fields and pastures new for the smallest increment of pay. No one, we think, would venture to contend that the post of municipal electrical engineer is not a position of trust and responsibility; and it never occurred to any of our leading economists, even in their palmiest days, to settle by the higgling of the market the remuneration of men from whom integrity and fidelity were expected. As a picturesque writer once forcibly put it, we do not on the decease of a bishop offer his diocese to the clergyman who will take the episcopacy on the lowest terms; when ill, we do not drive a bargain with the nearest needy medico. But when an electric lighting committee have to fix their engineer's salary and select their man, they *do* for the most part drive what, by a business misnomer, is called a *good* bargain. They fail to realise that even if it be granted that from the single point of view of engineering knowledge there may exist a plethora of fully-qualified men, the position they are, so to speak, thus putting up to Dutch auction, is one requiring tact, management, method, resource, and above all integrity; it is a position of trust and responsibility, and as such worthy of a generous salary. Indeed, by no other process is a good man likely to be secured. Experience seems, indeed, in one or two instances to have driven the obvious fact home to the municipal mind that two or three hundred a year is not exactly the right thing to throw to an engineer capable not only of economically and smoothly running an important central station, but of designing all extension work, drawing up specifications, settling tenders, and acting as a veritable *deus ex machinâ*. We do not doubt for one moment that plenty of young fellows, certificated up to the crowns of their heads, can be obtained who will be willing to try and accomplish all these things, and as many others as one likes to ask them, for £15 a month. The question is, can they be *trusted* to do them. Is it expedient, we had almost said is it right, to place anyone in a position of responsibility, and omit that important factor in the equation to his salary? A young—and quite incompetent—embryonic electrical engineer was once offered the magnificent salary of 10s. a week, or about 2d. an hour, to take charge of the isolated electric lighting plant of a large place of public resort, the lighting being carried out by a wheezy, semi-portable engine, a miscellaneous collection of antique dynamos, and a drunken stoker. "It is quite true I am a raw hand," replied the budding Faraday, "but the responsibility of the job would make ten times ten shillings a week none too much." And he was right; though he was promptly turned off for his pains.

NOTES ON SUBMARINE CABLE WORK.

BY H. D. WILKINSON.

(*Continued from page 55.*)

36. Polarisation of Fault or Break.—A little examination into the action called "Polarisation" will repay attention. The effect can be watched closely by an arrangement such as shown in Fig. 107.

Into a glass beaker filled with sea water is put a small piece of gutta-percha covered wire, W, the immersed end being bared and exposing some of the copper wire. Opposite to this in the water is a piece of galvanised iron wire, E, twisted to afford a good surface. The two pieces are held steady in a glass by bending their outside ends close to the glass and putting rubber bands round to hold them.

On connecting up five Leclanché cells with the zinc pole to the copper wire, a stream of bubbles of hydrogen is observed to be given off from the end of copper exposed. We may regard the piece of insulated wire as part of a cable, and the exposed bit of copper the fault or break, while the iron takes the place of the sheathing wire of the cable. It is very good practice to use such an artificial fault with a resistance of, say, 1,000 ohms in circuit, and then connect up to a bridge and measure the resistance with reversals of current, noticing the rate and amount of polarisation with each current. If the wires of the battery are reversed and a copper current sent into the insulated wire, the bubbles cease and the resistance goes up. The galvanometer will also show the direction of the current of polarisation, and its rate of fall after the testing current has been taken off.

Digitized by Google

A good insight can be obtained into false zero testing with such an artificial fault, especially as there is no interference from electrostatic discharge, as in a cable.

With a zinc current the action is to deposit a sulphate base containing oxygen on the exposed copper at the fault, and thus "seal" it up. In other words, the deposit of salts which almost instantaneously forms on the copper increases the resistance of the fault, because it covers it up from contact with the sea.

In low-resistance faults, or those which have comparatively large exposed area, the action is not so rapid as to prevent a reading being obtained; but, with a fault of small exposure and high resistance, it is risky to touch it with copper current, as it runs up immediately into hundreds and thousands of ohms, and sometimes the zinc current will not break it down again. The fault generally falls in resistance when the zinc current is put on, but not always. Sometimes it

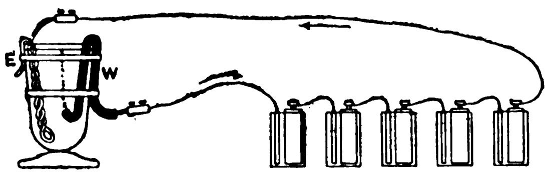

Fig. 107.

polarises up, and this happens only with small exposures at the fault, or exposures of such a character and position that the hydrogen gas evolved cannot easily escape. The gas then collects on the surface of the exposure, and insulates it from the water. When this happens it is best to test with reversals.

37. Improved Blavier.—This is a test from one end of the cable only, and, as is well known, consists in taking bridge measurements when the distant end is freed and earthed successively. The improvement, due to Mr. Kennelly, in the method of using this test consists in arranging the current through the fault to be the same when taking both measurements. With the same battery, of course, the current through the fault is stronger when taking the "free" than the "earth," and a resistance has to be inserted in the battery circuit when taking the "free."

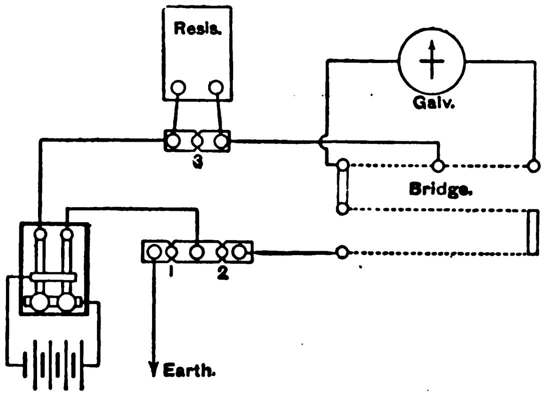

Fig. 108.

To find what this resistance must be we have to make a few trials. First, take the ordinary test without any resistance, from which we obtain the approximate values of x by the well-known formula:—

$$x = \mathrm{E} - \sqrt{(\mathrm{F}-\mathrm{E})\,(\mathrm{L}-\mathrm{E})},$$

where E is the earth reading, F the free reading, and L the copper resistance of the whole cable.

By equating the currents through the fault in the two readings, we obtain a formula for the approximate resistance to add, namely,

$$\frac{\mathrm{F}-x}{\mathrm{L}-x}\times\frac{\mu}{1+\mu}\left(a+x+b\frac{1+\mu}{\mu}\right)\text{ ohms,}$$

where μ is the ratio between the fixed arms of the bridge, a the resistance of the smaller fixed arm, and b the resistance of the battery. If even bridges are used, the ratio μ is unity, and the resistance to add to the battery becomes

$$\frac{\mathrm{F}-x}{2\,(\mathrm{L}-x)}\left(a+x+2b\right).$$

Adding the resistance so obtained a second set of readings is taken, and the resistance again worked out by the above formula.

After one or two pairs there is very little change to make in the resistance, and we may then take it that the resistance so added to the battery circuit is such that the current is the same through the fault in both tests of a pair.

This resistance must be short-circuited when taking an earth, and when a satisfactory pair has been obtained the correct value of x is found by the original formula. Mr. Kennelly recommends using only one direction of current to line and reading to false zero.

The arrangement shown in Fig. 108 is convenient for this and other similar bridge tests. For the earth reading all three plugs are put in, and for the free the plug 3 is removed, thus throwing in circuit the resistance added to the battery. Plugs 1 and 2 are used for loop test, 2 being in for metallic circuit and 1 for the loop.

If the fault varies much, the resistance to add may work out too high, and the result of having too much resistance is to make x too little or to "bring the fault home." And the more the fault is brought home the higher the resistance to add works out, thus making matters worse, which may result in putting the fault on the testing table unless it undergoes some other change. When a fault is behaving like this there is nothing to guide one but experience.

38. Mance Partial Earth Test.—Sir Henry Mance, to whom this test is due, first introduced it to notice in his Paper "On a Method of Eliminating the Effects of Polarisation and Earth Currents from Fault Tests" read before the then Society of Telegraph Engineers and Electricians in May, 1884.

The distant end being free, a pair of observations are made on the bridge in the ordinary manner with different bridge ratios. The battery key is kept down all the time with zinc to line, and the bridge balanced to instrument zero (Fig. 109). The test may be stated thus:—

With equal ratio a/a in bridge, balance obtained is A ohms.
" " " a_1/a_1 " " " " B "
Resistance of battery b ohms.

Reading to instrument zero the galvanometer is in its most sensitive condition, and there is a further advantage in being easier to balance to instrument zero than to false zero. On the other hand, the sensitiveness of the galvanometer is different in two readings of a pair on account of the different bridge ratios.

By changing the ratios of the bridge, the strength of current to line is varied; and for each strength of current two equations are derived by Kirchoff's laws, one containing the E.M.F. of the battery, and the other the sum of the disturbing currents. Combining the four equations, the battery E.M.F. is eliminated, and so also are the disturbing currents, assuming, however, that they remain constant during a pair of bridge readings. So far as the earth current is concerned, it may be assumed that it does not seriously alter if one test of a pair follows the other fairly rapidly. When taking a set of pairs it is a good plan to change the adjustable resistance before changing the ratios. Thus, supposing we have just balanced to B ohms with ratio a_1/a_1; then alter the adjustable resistance to A ohms before changing the ratio back to a/a. A little further adjustment will then bring to balance.

If a/a is 100/100, and a_1/a_1 1,000/1,000 as recommended, B will exceed A, and we have:—

$$\left.\begin{array}{l}\text{Resistance of cable up to fault, } plus\\ \quad\text{resistance of fault}\end{array}\right\} = \frac{\mathrm{A}\,(2\,b+a_1)-\mathrm{B}\,(2\,b+a)}{(a_1-a)+(\mathrm{B}-\mathrm{A})}.$$

If a_1/a_1 is less than a/a, and in consequence B is less than A, the formula becomes:—

$$\frac{\mathrm{B}\,(2\,b+a)-\mathrm{A}\,(2\,b+a_1)}{(a-a_1)+(\mathrm{A}-\mathrm{B})}.$$

Therefore, when testing from one end only, in order to obtain distance of fault we have to judge (by its behaviour under

Digitized by Google

test, and a lot of experience) the resistance to allow for the fault, and deduct it from the result obtained by the formula. Actually somewhat less than the resistance of the fault must be deducted on account of the fact that the formula assumes the fault to remain constant during a pair of readings, which (in consequence of the current being changed) it does not. When possible, the test should always be taken from *both* ends, so as to cancel the uncertain quantity of fault resistance.

Sir Henry Mance, in advising tests from both ends, recommends a resistance being added to the end of cable nearest the fault, so as to make the actual resistance in circuit the same when testing from either end. Then, by using testing batteries of approximately the same E.M.F. and resistance, and similar bridge ratios, the current through the fault is the same, and its resistance constant for the time being.

The resistance to add is soon found by working out one or two pairs from both ends, each end freeing in turn. The following is the procedure.

Take a pair of readings with zinc and copper, the other end being free, and work out result by formula. Free while the other end tests. The difference of the two results in ohms is then added to the end of cable nearest fault. Take readings from each end again as above. Call result A that obtained at end nearest to fault (after subtracting resistance added to this end), and result P that obtained at the other end. Then distance of fault in ohms from nearest end of cable is

$$\frac{L + A - P}{2} \text{ ohms},$$

where L is the normal copper resistance of the whole cable. When it is possible to test from both ends in the above manner the results are very reliable if taken fairly rapidly in succession.

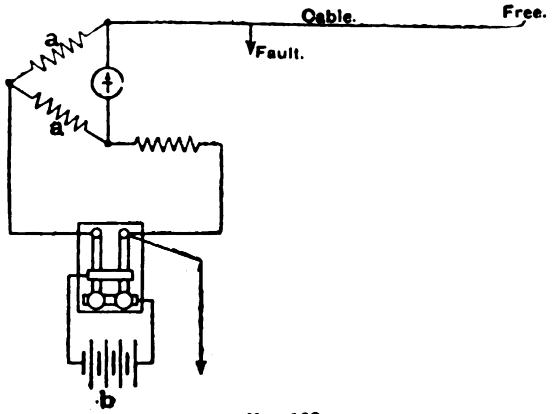

FIG. 109.

A wider range in varying the testing current can be attained by the use of different resistances in the battery circuit instead of different bridge ratios, with the additional advantage that the sensitiveness of the galvanometer remains constant. A pair of readings is taken as follows :—

With equal ratio a/a and total resistance b in battery circuit, balance obtained is A ohms. With same ratio and total resistance b_1 in battery circuit, balance obtained is B ohms. (Resistances b and b_1 both include the resistance of battery and whatever extra resistance is added to vary the current.) If B exceeds A as before (by having b_1 greater than b) we have—

$$\left.\begin{array}{l}\text{Resistance of cable up to fault,}\\ \quad\textit{plus}\text{ resistance of fault}\end{array}\right\} = \frac{A(2b_1 + a) - B(2b + a)}{2(b_1 - b) + (B - A)}.$$

If we use b_1 less than b, and B is consequently less than A, the formula becomes

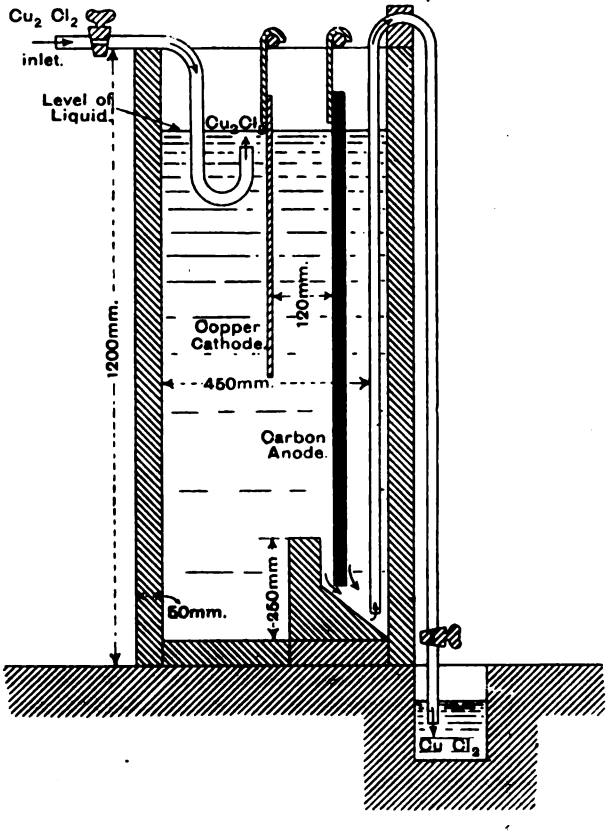
$$\frac{B(2b + a) - A(2b_1 + a)}{2(b - b_1) + (A - B)}.$$

Taken in this manner also the test is subject to the same strictures as mentioned above, and in all cases should be taken from both ends where possible, and the two results combined as explained to eliminate resistance of fault. Incidentally it may be mentioned that on a good cable, when testing for copper resistance, the Mance method is very useful, as it eliminates the effect of earth currents, and these are often very troublesome. Needless to say that the test is then quite accurate from one end only, as there is no fault and no polarisation current. The above formulæ give the copper resistance at once.

(To be continued.)

THE ELECTROLYSIS OF SOLUTIONS OF CUPROUS CHLORIDE.

The following account is an abstract of a Paper by A. Coehn and O. Lenz, appearing in the *Zeitschrift für Elektrochemie* of April 20th. The authors, after referring eulogistically to the Höpfner process, the underlying idea of which is the use of cuprous instead of cupric solutions for the commercial winning of copper, describe a series of experiments designed to determine the conditions under which a solution of cuprous chloride yields smoothly per unit of current twice the amount of copper given by a solution of a cupric salt, *e.g.*, ordinary sulphate of copper.



The chief objection to the well-known Höpfner process—granting the efficiency of the anode liquor to extract copper sulphide ores, and to become by that act reduced to the cuprous condition —arises from the need for a diaphragm. In the absence of some division between the liquor at the anode and the cathode, the copper upon the latter is speedily dissolved by the cupric chloride produced at the former, and a poor yield, falling far short of double the quantity given by a cupric salt, is obtained.

The apparatus shown in the figure indicates the arrangement ultimately found to meet the requirements of the case. The design is obvious from the figure, the only comment necessary being that in the actual apparatus the inlet tube for the solution of cuprous chloride is not on one side on the cathode, but is situated between a pair of cathodes similar to that shown singly in the illustration. During the process of electrolysis, copper is deposited from the cuprous chloride on the cathodes, and the cupric chloride appearing at the anode forms a heavy solution underlying the solution of cuprous chloride, and removable by the syphon shown on the right-hand side of the figure. Stripping of the copper from the cathodes by the action of cupric chloride is avoided by the shortness of the cathodes, which end on a line above the level of the junction

Digitized by Google

of the cuprous and cupric liquors. The electrolyte best fitted to give a quantitative yield of copper (approximately double the weight of that precipitated in an ordinary copper voltameter) is one containing cuprous chloride in amount corresponding with 4 – 15 grammes of copper per litre, held in solution by means of sodium chloride (50 cubic centimetres of a 30 : 100 solution for each litre) and a little hydrochloric acid. Any current density up to, but not beyond, 20 amperes per square metre could be used without deteriorating the quality of the coating of copper deposited.

THE REDUCTION OF REFRACTORY METALS.

The increasingly common use of means of decomposing highly stable substances, such as metallic oxides having high heats of formation, on a scale greater than that generally adopted in the laboratory, has within the last few years attracted the attention of the technical public to questions, intellectually interesting, and possibly commercially attractive, which would otherwise have remained untouched save by the eclectic few. No one has done more, in this country, to spread and popularise a knowledge of the properties of those metallic elements, which are more more familiar by name than by appearance even to professional chemists, than Prof. Roberts-Austen. In continuation of previous expositions, he recently gave a *résumé* of modern work in this direction, in the form of a lecture at the Society of Arts, illustrated by well-chosen experiments. Seeing that the title of the discourse was "The Reduction of the Rarer Metals from their Oxides," it is evident that the term "rare" was used in reference to the metals in their isolated state, *i.e.*, palpably as metals, and not in the chemical sense of "rare," viz., very seldom found, whether in the metallic state or as a compound. Chromium—and, until the last few years, aluminium—may be called rare in the former, but not in the latter sense. By accepting the less usual connotation, a good many fairly commonplace elements may be elevated to a temporary position of rarity, and brought within the scope of a Paper with the title already quoted.

At present three distinct methods of reducing refractory metals are in common use. It is proper to remark that by "refractory metals" is meant that class of metals, the heats of combination of whose oxides are too high to allow of their commercial reduction to metal by means of carbon at temperatures up to and including those of the blast furnace; the canon is not absolute for certain metals, notably those of the alkalies, which are sufficiently volatile and may be reduced by means of carbon in spite of their essentially refractory character.

The first of these three methods in point of antiquity, general applicability and inherent interest, is the purely chemical process of performing the reduction in two or more steps, some intermediate compound forming the stepping stone. The most familiar illustration is the reduction of aluminium from alumina *via* aluminium chloride. Carbon will not reduce alumina at ordinary furnace temperatures; sodium is also ineffective; carbon will not reduce aluminium chloride. But carbon in the presence of chlorine will convert alumina into aluminium chloride, and sodium will reduce this latter with ease. The general aim in this method is to convert the refractory substance into a compound less markedly refractory, so that it can be dealt with by some fairly cheap reducing agent—the position is sapped, not stormed. Of all the compounds of aluminium which have seemed likely to serve as half-way houses in the process of reduction, the sulphide has always been one of the most attractive to the devisers of processes. It is not easy to prepare the sulphide, the reaction of carbon disulphide on alumina needing a high temperature for its accomplishment, but the task is light compared with the commercial reduction of the sulphide to aluminium; the metal manganese is the only likely candidate for the contest. Fortunately, the utilisation of aluminium sulphide has been achieved by other means. A variant of this general method is to use some reducing agent, itself frequently obtained by two or more steps, more powerful than carbon under the particular conditions of experiment. The reduction of chromium by the action of aluminium on chromic oxide is a case in point. The aluminium for this purpose may be looked on as carbon that has suffered a sort of chemical step-up transformation (the transformer having, by the way, a somewhat low efficiency), and it is able to accomplish the reduction with corresponding ease. This manner of utilising the energetic essence as distinct from the material accidents of the carbon, is of particular value, when—as often—the metal to be reduced has a tendency to form a carbide. The carbon being represented solely by its astral body, is secure from material union. Both chromium and manganese are much used in steel making, where the fortuitous introduction of carbon is undesirable, and the preparation of these metals and of their alloys with iron, free from carbon, is consequently of industrial moment.

The second method is noteworthy for its extreme neatness and simplicity, and the certainty that the reducing agent will not introduce foreign matter into the reduced product. It is, of course, electrolysis. Unfortunately, as the metals to be reduced are *ex hypothesi* refractory, they cannot be dealt with in aqueous solution until someone has discovered a new kind of water less readily electrolysed than the ordinary variety. The adoption of fused baths presents many difficulties, largely arising from the attack of the vessels in which the electrolysis is carried out; but that these are not insuperable is proved by the flourishing state of the aluminium industry, the bulk, if not the whole, of which now depends on the electrolysis of alumina or its salts. It is here that the utility of aluminium sulphide is shown, for although its chemical reduction is difficult, its electrolysis can be accomplished, and presents certain advantages over that of the oxide dissolved in a fused halogen salt of aluminium, which is the more usual electrolyte.

The third general method is that involving the employment of the electric furnace. On account of the high-fusing point and boiling point of carbon, this element can be trusted to stay at its post by the refractory oxide until a temperature is reached at which reduction of the oxide takes place. When once this is accomplished the carbon escapes as the gaseous oxide CO, and reverse reaction is thus minimised. But the very merit of carbon is the bane of the process when a pure metallic product is required. At the high temperatures requisite for reduction, carbides of great stability are formed and from these the pure metal can only be obtained by repeated fusion with the oxide of the metal under treatment, in order to successively oxidise portions of the carbon by an oxidant from its nature incapable of reacting upon the metal itself. The *rationale* of the action of the electric furnace in reducing refractory metals it totally distinct from that of the electrolysis performed upon a fused salt of the same refractory metal. The latter is, above all, as systematic and selective as the former is chaotic and indiscriminate. Each serves special ends.

In considering experimental work of the nature of that touched upon in the foregoing lines, a certain sobriety of thought and statement is indispensable. There is but little lately accomplished in the production of any of the refractory metals which has not been performed years ago by the chemist engaged in purely scientific research. The only justification for satisfaction concerning these larger scale experiments, and their easy and brilliant execution, is the consequent device of industrial methods and the discovery of some means of utilising the products. Much nonsense is talked about possible new structural metals, the orators forgetting that the abundance of an element on the earth's surface is a weighty factor in its utilisation. Glucinum is no doubt a nice material for many purposes, and its reduction is not beyond our means; but unhappily there is, so to speak, none of it. Even given abundance and fair ease of production, a "new" metal must be shown to be in some respect better than the older group before it can be more than a curiosity. Much more is to be hoped from persistent and enlightened experiment on the influence of small quantities of the more refractory metals on those longer and better known in the metallic state, with the view of obtaining alloys superior to those in common use.

King's College Old Students.—We have been requested to announce that the annual dinner of old students of King's College will be held at the Holborn Restaurant, on Monday, June 24th, with the Bishop of London in the chair.

ROTARY-CURRENT AND ALTERNATING-CURRENT DYNAMOS OF THE ALLGEMEINE ELEKTRICITÄTS-GESELLSCHAFT.*

BY M. VON DOLIVO-DOBROWOLSKY.

The relatively large number of poles in alternating-current machines which were necessary to reach a high number of alternations at a small number of revolutions, rendered an economical design of the field-magnets most difficult. A certain saving was, however, effected by using one field-winding to do the whole work,

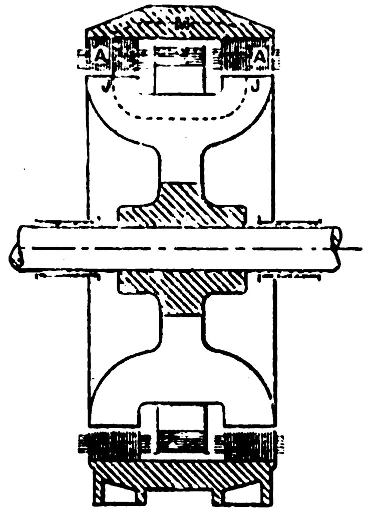

FIG. 1.

nstead of exciting each pole separately. The first alternator of this kind was probably that of Klimenko of Charkow, which was exhibited at the Vienna Exhibition in 1883. The bad proportionality in the design of this machine prevented it from coming into a more general use. The Mordey alternator of the latter end of the eighties, which is really derived from the Klimenko machine, was, in fact, the first practical useful machine with a single-coil magnet. To-day there are many modifications of this type of machine in existence, as, for instance, the one built by the Maschinenfabrik Oerlikon with Brown's inductor, and several others. One might predict that the single-coil magnet arrangement will come so to the front in the construction of alternators in the same way as the ring-

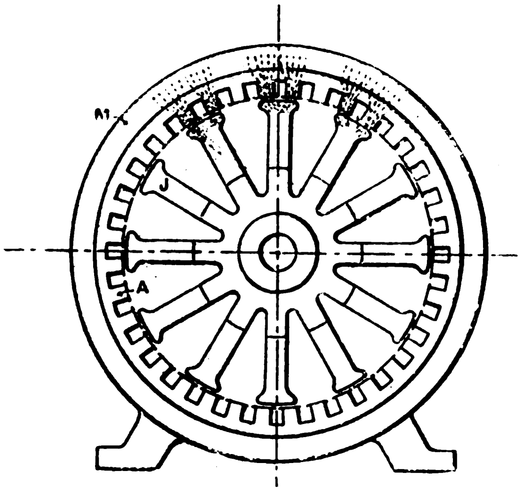

FIG. 2

pole arrangement with radial magnets has, in the case of continuous-current dynamos, displaced all former forms of magnets. Besides its main advantage, economical excitation, the exciting coil of a single-coil magnet in some of its forms may be made stationary so that only the magnet core with its poles revolves. The 1883 machine of Klimenko was without any revolving wires. On the Mordey alternator the magnet coil could also be made stationary, the reason for not doing this in practice lies entirely in the mechanical difficulty of securing the relatively heavy coil to the light disc armature in a workmanlike way. After this introduction, I come to the description of two types of alternators built by the Allgemeine Elektricitäts Gesellschaft of Berlin.

Both types belong to the single-coil magnet class with stationary winding. The first kind, shown in Figs. 1 and 2, is most suitable for high speeds, consequently for belt or rope driving. From both illustrations it will be seen that the magnetic circuit is completed by the outer case M, the two armature rings A, which are built up of laminated iron, and the tooth-wheel or turbine-wheel inductor J, which latter is shown separately in Fig. 3; S is the exciting coil, and is fixed to the frame M. The pole-pieces of the inductor-wheel give rise on the inner face of the armature rings to points of very uneven distribution of field, so that by rotating the inductor the armature coils, which are to be seen in Fig. 2, receive an induction through the number of lines of force which flow in them being changed. On the outer face of the armature A the distribution of field is homogeneous, and therefore nothing prevents the lines of force being led through the frame M. Here I will remark at once that similar machines have lately been built by Stanley in America, and also by Sollman, of Wahl and Co., in Russia. The

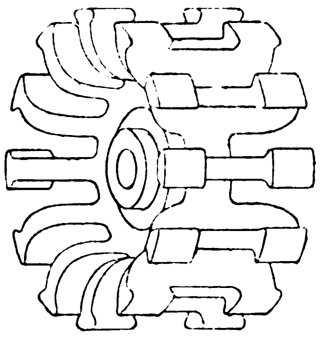

FIG 3.

Sollman alternator was described in the Russian *Elektrotechnische Zeitschrift* a little time ago. A number of alternators of this type have been designed, some also with the modifications as shown in Fig. 4. A 100-H.P. "drehstrom" generator of this type is now at work at the sugar refinery of Messrs. Schwengers Söhne, at Uerdingen, on the Rhine. Of course this kind of machine is suitable for either single-phase, multiphase, or "drehstrom"

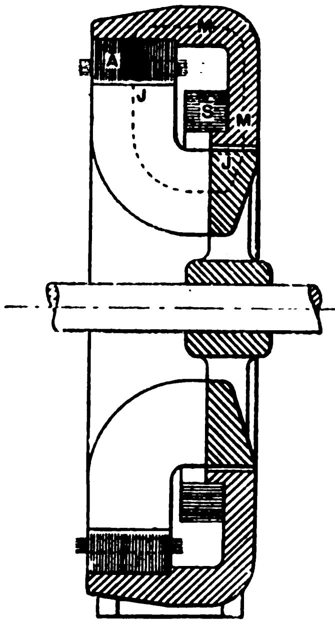

FIG. 4.

current. In Fig. 2 the number of armature coils is three times as large as the number of pole shoes, whereby three currents of 120deg. phase difference are produced. Instead of the "pole-like" (*poligen*) arrangement of the armature winding, the opposite coils can be connected, which is admissible for machines of low voltages, and sometimes even an advantage. In larger size machines the bar winding can be used, as shown in Fig. 5, where each of the coils consists of only one copper bar. Three machines of this type, of 300 H.P. each, are at present under construction at the works.

Besides this type of machine, which is, as stated before, more to be recommended for the high speed, we are also building a slow-

* Paper read before the Elektrotechnischer Verein, and translated from the *Elektrotechnische Zeitschrift.*

Digitized by Google

speed machine of a smaller width, but greater diameter, suitable for direct driving. The same is also on the Klimenko principle. Figs. 6 and 7 show clearly that the magnetic lines generated in the large exciter coil S run evenly through the iron ring M and the two armature rings A when the magnetic circuit is closed by pole-pieces P. When these pole-pieces, which are fixed to the flywheel of the engine, rotate, points of high magnetic density evidently travel along the surface of the two armatures, and the armature coils, which are clearly shown in Fig. 6, receive an induction. Things can, of course, be also arranged for multiphase currents by simply using a proper number of coils relatively to poles. "Drehstrom" dynamos of this class are at present being built for the Electric Supply Station at Strassburg, viz., three of 400 H.P., and two of 200 H.P. each.

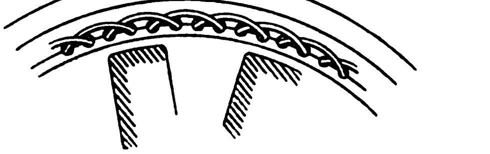

FIG. 5.

Besides the advantage of having no collecting brushes, the little attention which these machines require, the simple and strong construction, is at once evident even from the illustrations. It is impossible to touch the high-pressure coils when the machine is running, as the revolving flywheel in front of it prevents this. When repairing, the whole frame can be moved back, and the armature winding becomes easily accessible. As to the electrical advantages of this type of machine, two must be specially mentioned, first the economic excitation, secondly the very small drop of potential. Some consideration should also be given to the naturally small hysteresis, which, in combination with the little exciting current required, enables an especially high efficiency to be obtained, even at light loads. To demonstrate these advantages by data, I will give you the principal figures of the 400 H.P. machine

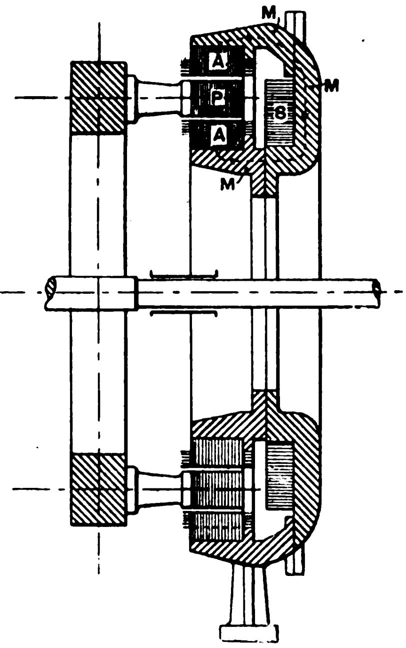

FIG. 6.

for the Strassburg station :—Output, 280 kilowatts at 2,750 volts; revolutions, 150 per minute; number of poles, 40; weight of copper of magnet coil, 730 kilogrammes; weight of copper of both armatures, 200 kilogrammes; excitation required, 4 000 watts—about 1·4 per cent.; total watts consumed in both armatures = 2 per cent.; total hysteresis loss about 1·3 per cent. This machine requires, in spite of the small loss, only a little over 2 kilogrammes of copper per horse-power. The ratio of the effective ampere-turns of one armature coil to the ampere-turns of the exciter coil is about 1·15.

That the weight of iron is not in consequence very high the following figures will show :—

Frame	6,000 kg.
Both armatures	2,000 „
Pole-pieces	750 „
Total weight of iron exclusive of shaft and bearings	8,750 „

Before I conclude, I would like to refer once more to the discussion of last meeting on the most suitable fall of potential in alternating current dynamos. As is known, Hopkinson in the eighties found by calculations that for the synchronous running of two alternators a certain ratio between resistance and self-induction was most suitable, and that the self-induction had the most important *rôle*. From this many concluded that plenty of self-induction must be provided, as it is nearly impossible to calculate the Hopkinson ratio in advance. But often the machines got too much of it, and the consequence was, the thing would get out of parallel. This was explained by saying there was still not enough induction, and we eventually tried to bring the machine to such a point that by means of self-induction it could not give more than 1½ times its normal output. Mordey, at the end of the eighties, maintained just the contrary, *i.e.*, that alternators should have little resistance and little self-induction. The smaller the fall of potential of the machine the easier large currents could be got out of it. However, the most practical and demonstrative proofs of Mordey could not at once shake the general belief in self induction, and the dispute is still unsettled to-day. Of course, after the many experiments with alternators with a small fall of potential, which have been proved to run just as good in parallel as alternators with a large one, certain theorists have moderated their demand, and in fact are already satisfied with a fall of potential of from 15 to 20 per cent. I think one can predict that dynamo constructors will soon come to the general opinion that a little fall of potential more or less is of no consequence to good parallel running, especially as there are no practical proofs that too little resistance or self-induction has ever prevented alternators running in parallel satisfactorily. When, however, neither parallel running nor the conditions of

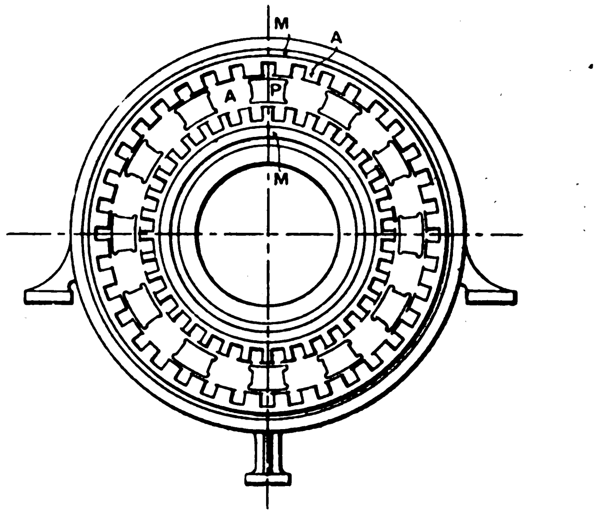

FIG. 7.

synchronism require a large fall of potential, the most important argument for building alternators with self-induction disappears. The fall of potential has many disadvantages which are specially felt in motor driving. The wattless current component operates with its full ampere-turns in the direction of the magneto-motive force of the primary machine, therefore with motor currents one has a bigger reduction of the magnetic field than with lighting currents, and a machine of the latter class with a fall of potential of 15 per cent. is therefore not suitable for satisfactory motor work. If we consider that small motors seldom have cos ϕ more than 0·7, and large ones scarcely above 0·87, and, on the other hand, figure to ourselves that the wattless component amounts of from 0·7 to 0·5 of the whole current, we can easily perceive what a detrimental result the above mentioned subtraction of ampere-turns must have. As, however, at the present time the motor question requires the greatest consideration on the part of electric supply stations, doubtless the question of dynamo design will be answered in one way only, that is, to have the smallest possible fall of potential. No lowest limit can be fixed to this, as even the best of existing machines are far from being perfect in this direction. In my opinion, and according to my experience, it is entirely necessary and quite possible that the fall of potential due to the lighting current should not exceed 4 to 5 per cent., as even then we have still at full load with motor current a fall of from 15 to 20 per cent. The only intelligible reason which was brought forward against such machines is the danger of short-circuiting. Experience with continuous currents has taught us, however, that the dynamos are better protected by good fuses and automatic cut-outs than by a counter-compound winding. Therefore with alternating current —"drehstrom" work—we can very well do without the self-induction, which otherwise only deteriorates the machine.

Digitized by Google

In conclusion, I should like to remark that in the last part of my Paper I have treated the self-induction and armature reaction to a certain extent as one, which is not quite correct. However, it was rather an explanation of the self-induction itself I wished to give you to-day than its origin and calculation. Besides, both phenomena are very nearly related and generally appear together, and are of the same order, so that machines with much reaction have likewise large self-induction and *vice versâ*.

ON THE RECENT DEVELOPMENT OF THE SINGLE-ACTING HIGH-SPEED ENGINE FOR CENTRAL STATION WORK.*

BY MARK ROBINSON.

1. The success of the high-speed engine in this country is amongst the notable engineering facts of the time. It relates, in the first place, to mechanical engineering, yet it also concerns this Institution, since it is electrical engineers who are the chief users of high-speed engines; to them, in fact, it is due that such engines hold their present important position.

2. The Presidential Address at the commencement of the present session, in which the high-speed engine was favourably referred to, produced the comment in a leading professional paper, that electricians had little cause to boast about their work in developing high-speed engines, for if they "had stuck to the builders of mill engines and marine engines, instead of trying to strike out a new line of steam engines for themselves, electric lighting would have been very much the gainer." The judgment of electrical engineers has thus been arraigned before the general body of their brethren, and it may be useful to inquire with what justice.

3. According to what purports to be a full list of public lighting stations, published last January in one of the principal electrical journals, the indicated horse-power installed in all the lighting stations in Great Britain was 101,390. Of this, one make of single-acting high-speed engine accounts for 53,340 horse-power, or more than all other patterns put together, and even of these last more than 4,000 I.H.P. are high-speed engines of other kinds. Engines of the mill or marine pattern figure for little in the total, and as the high-speed engine started later than its rivals, its proportion of the more recent work is even greater than the above figures would indicate. Not much apology, therefore, is needed for bringing this subject before electrical engineers.

4. The preponderance of one type of high-speed engine, embodying many views in conflict with those upon which other engine practice is based, virtually obliges this Paper to be both a description and a defence, and may even give to it the appearance of eulogy, of that particular engine. Few but those directly interested in the manufacture of a highly-specialised machine are so conversant with it and its history as to be willing to write upon it; hence such a Paper risks the charge of partisanship, and is certainly open to that of prepossession. A well-remembered charm of the late Mr. P. W. Willans' Papers upon steam-engine economy lay in the fact that his conclusions were as far as possible framed to apply to engines in general; his own engine, though in all cases the one tested, was scarcely described, and certainly unpraised. The present Paper, on the other hand, if it is to have any practical value, must not only describe the Willans engine, but must deal almost exclusively with its difficulties, with its successes, and with its improvements. A description of the engine, with some notes on its history, is given in an appendix.

5. The advantages of single action and of high speed are, however, not limited to any one engine, and they may be described generally. An engine is "single-acting" when the steam acts only upon one side of the piston, the typical case being James Watt's Cornish pumping engine, and this method of using the steam has certain economic advantages in which a double-acting engine cannot share. At equal speeds, however, they are neutralised by the fact that, for a given power, the cylinder capacity has to be twice as great in a single as in a double-acting engine, and it is not until the single-acting engine runs at twice as many revolutions as its rival that it has much advantage. This it is usually able to do, since it can be worked upon the "constant-thrust" plan, which the double-acting engine cannot be; that is to say, the piston-rod can be kept pressing against the connecting-rod, and the latter against the crank-pin, not only throughout the working stroke, but through the return stroke as well; the working parts are thus always in compression, and *never* in tension. The cross-head pin presses always against the same side of the bush or brass in the small end of the connecting-rod; the big-end upper brass maintains constant pressure against the crank-pin, never leaving it even momentarily; the crank-shaft presses always against the lower main bearing brasses, never against the caps.* Of course, a single-acting engine is not necessarily a "constant-thrust" engine, and special means have to be taken to make it so: the point is that these means are possible with a single-acting, and are not possible with a double-acting engine, and though it is a view which is contested, it is the opinion of the author, and certainly it is a widely-held opinion, that really high speed and "constant thrust" should go together, unless in such a case as is referred to in paragraph 8.

6. High speed is at last recognised as a good thing in itself. A fast-running engine is, for a given power, smaller and lighter than a slow one, while a large number of small impulses per unit of time give a more even turning moment than a small number each of greater magnitude. By shorter exposure of the cylinder surfaces to successive changes of temperature, the loss by initial condensation is reduced, so that an unjacketed engine becomes as good as a jacketed one; and for many purposes, as where direct coupling to fast-running machines is required, and especially for dynamo driving, the high-speed engine has advantages which are of necessity admitted. Attempts to revive the belt-driving system in central stations, in the country which is the home of direct driving, and after the rest of the world has almost unanimously come round to its views, will be endured in England only so long as shareholders and ratepayers remain ignorant of the waste of money it entails, while the proposal to make the naturally fast running dynamo into a slow and enormously more costly machine, merely for the sake of allowing it to be driven direct by a slow-running engine, is not likely to meet with success in the long run. The future, however, can take care of itself; it is enough that high speed is already recognised as beneficial by all who are likely to mould future practice.

7. It is evident that a single-acting engine in which there is absolutely no back-lash and no reversal of stresses, and which is otherwise rightly proportioned, will run freer from wear in its brasses than a double-acting engine, at any but very moderate speeds. In the author's opinion an ordinary double-acting engine is in danger of becoming troublesome, if it is run much more than one-third as fast as the speed at which a single-acting engine will run continuously and easily; will need very good design and careful attention if it is to run half as fast; and must be an altogether exceptional engine if it is to run two-thirds as fast, without giving comparatively frequent trouble. There would probably be no difficulty in finding in use many single-acting engines of, say, 80 or 100 I.H.P., running at 450 revolutions per minute, which have had five years' service and upwards without one of the brasses being touched since the engine was first put to work, and it is a safe statement that if these brasses were now removed, in most of them no wear would be detected without careful measurement, while if, through unfavourable conditions of lubrication or otherwise, appreciable wear were found, it would be absolutely without effect upon the good running of the engine. No such statement could be made of any double-acting engine; but for any purpose where the runs are limited to hours, or even to days, an ordinary double-acting engine of the same power would no doubt run at 150 revolutions without giving appreciable trouble. Such an engine, however, would have larger cylinder volume than the 450-revolution single-acting engine, and would suffer more from initial condensation, and it would hardly be trusted by most engineers for purposes (such as electrolytic work) in which an engine must run for many weeks, or even months, without stop. With special design, half-speed, or 225 revolutions (giving equal cylinder volumes, but double exposure of the surfaces in each revolution), is also attainable by a double-acting engine; but few are likely to dispute the opinion that two thirds speed—*i.e.*, 300 revolutions per minute—is not a desirable speed for an 80 horse double-acting engine required to run continuously for weeks or months together under commercial conditions. The author does not overlook the fact that double-acting engines are designed and made to run at even the fullest speeds of single-acting engines, and that by a combination of excellent design and workmanship with a system of forced lubrication (oil is forced into the bearings by pumps) they are able to do so. It would be out of place to refer here in detail to the author's reasons for disbelief in the ultimate acceptance of this ingenious and bold attempt to evade the natural difficulties which the case presents; it is sufficient to say that for the present the single-acting engine holds the field for high-speed work on the large scale, and, according to the most recent experience, with increasing success. Defining high speed as the highest speed which experience shows can be attained without visible disadvantage by a single-acting engine of a given power, it must be said that single action is not essential to high speed, but that it helps enormously to its successful attainment.

8. It may nevertheless be of interest to remark (though, in the author's opinion, the fact has no bearing upon electric lighting practice) that for the attainment of the extremest speeds, with

* Paper read before the Institution of Electrical Engineers

* A single-acting engine can be run with the parts always in tension, and never in compression, with equal ease; but the contrary plan is practically the best

Digitized by Google

large powers, a double-acting engine is to be preferred. The maintenance of constant thrust upon the brasses, which may be taken as the real essence of a single-acting engine, involves great difficulties when certain limits are exceeded, and if, through any temporary reason, the constant thrust is lost, and the engine becomes double acting as to its brasses, there will be serious chances of rapid wear, and even of such hammering as to cause fracture. In a double-acting engine, on the contrary, provision is made from the beginning for the change of stress at the end of each stroke; it is a mere question of brute strength in the parts, and since they are always under observation for excessive wear, and periodical adjustments are a part of the system, there is little danger of serious damage. For torpedo boats and other cases where the greatest power must be obtained from the least weight, and where knock and frequent adjustment are comparatively unimportant, double-acting engines are plainly best. But few electrical engineers would care to entrust the continuous running of their stations to engines of this type, or to go through quite the same engine-room experiences as are rightly accepted on board a "catcher."

9. The class of engine called "high speed" in America is usually a double-acting engine, capable of running from one-half to two-thirds the speed of the corresponding single-acting engine of this country. As such, it has already been referred to generally, and though it usually runs well, it has no claim to special consideration, certainly not on the ground of economy.

10. The effect of "single action" in lessening wear upon the brasses must be obvious, and the connection is almost as close between single action and the beautifully simple method of automatic lubrication by the splash of the cranks in an oil chamber; the latter cannot be adopted without risk of much inconvenience, where brasses have to be under constant observation. The very small bearing friction, which results partly from this system of lubrication, and partly from the absence of back-lash, is also unattainable in a double-acting engine, except the special packing rings, and those only by completely duplicating them upon each piston.

11. So far only the general and more obvious advantages of the single-acting engine have been considered. Now it is proposed to describe in some detail three important features in the particular engine which has become, in this country at least, the type of the class; none of them have yet attracted as much attention as, perhaps, they deserve. They are:—

(*a*) The special system of packing rings for pistons, valves, and glands.

(*b*) The special provision for internal drainage.

(*c*) The Cornish cycle, or "transfer plan."

All three are directly related to the single-acting principle. All, except the Cornish transfer, are peculiar to the Willans engine, and none of them could possibly be adopted in a double-acting engine. All are of high value in promoting steam economy.

12. *Packing Rings* (*a*).—One of Mr. Willans' latest improvements in his engine was the system of packing rings shown in Fig. 1, where A is the working end of the cylinder; the pressure in B, below the piston, is materially less upon the down (or working) stroke than that above it, but on the up or exhaust stroke it is practically the same; it is never less, unless in the exceptional case of a looped diagram. There are two rings, *a* and *b*, breaking joint, and turned of the same thickness throughout, which exactly fit the cylinder before they are divided; *c* is a cast-iron spring ring, turned eccentric and slightly too large for the cylinder; great care is taken to have true surfaces at *x*. The follower F is a thin steel plate, very slightly dished, so as to have a slight initial pressure upon the top of the rings. It is perforated, to let steam from A enter the space behind the spring, which it tends to push outward lightly during the up-stroke, comparatively strongly during the down-stroke. The rings are held against the lower flange of the piston body G, not only by the spring follower F, but by the steam pressure on the top of the rings; on the up-stroke, when there is less pressure above the rings, their friction against the cylinder is sufficient to keep them seated on the piston body. It will be noticed in this system, first, that the outward pressure of the rings *is relieved during the ineffective stroke*; and, secondly, that the principle of "constant thrust" is applied to the rings as regards end-play. At all times, whether the piston moves one way or the other, and equally while it reverses its movement on the dead points, the piston rings are held closely down upon the piston flange, and there is none of that wear of the rings endways which tends to arise in all double-acting engines, owing to the friction of the rings causing them to lag behind, so that they are pushed one way by the piston body and the other by the junk ring or follower. Even if wear arose (which under ordinary circumstances it cannot) the spring follower *would follow it up*: there would still be no hammering of the ring between the two sides of the groove. There is thus no increase of ring leakage; the longer the use the tighter the rings. The piston valves are on the same system as regards constant pressure of the rings and other parts against each other, but they are not steam packed (*See* Fig. 3). They are separated by suitable cast distance pieces, with their ends faced to lie against the rings. All are strung together upon a steel tie-rod, with a kind of spring washer under the nut at the end. All parts are free to slide upon each other sideways; all are designed to be held together, without the possibility of hammering upon each other, by the pressure of the steam (in the steam chest) upon the uppermost valve, aided by the spring washer referred to. The gland rings, used instead of stuffing boxes (*see* Fig. 4), are upon exactly the same system as the main piston rings; they are simply piston rings pressing inwards instead of outwards, and guarded against end-play in exactly the same manner. Steam is admitted behind them as in the main pistons.

13. This construction of the various piston and other rings is perhaps the most interesting application of the constant-thrust principle in the engine, but it has not been arrived at without long experiment and some changes. It was originally attempted to dispense with steam pressure behind the piston and gland rings—in fact, to exclude it; and many will remember the collapsing of the rings, especially when the steam was very wet, or when over much oil was used. Under some circumstances a ring could always be set collapsing by increasing the oil supply; it is an old experience that water (or oil) will get behind a ring where steam alone will fail to pass. Once separated from the cylinder wall, the ring was bound to spring inwards, until stopped by the butting of its ends; this butting and the subsequent spring outwards caused much noise and wear, and sometimes breakage of the ring, with, of course, waste of steam. Instead of a spring-plate follower, there was at first a fixed follower—which allowed end-play, and so wear, as in other engines—and afterwards a solid follower pressed down by spring washers, which also was not satisfactory. When "steam packing" was first adopted the holes in the follower were not made large enough to let the full pressure in behind the rings in the short time available, and so the system was imperfect. These defects have been corrected, and the system seems now to be not only perfectly successful, but in a sense beyond rivalry; for it would evidently be impossible to apply it in a double-acting engine—that is, in an engine where the

Digitized by Google

preponderance of pressure changes from one side of the piston to the other, except by absolutely duplicating the packing arrangements of each piston. It may be added that very careful measurement, based upon some three years' experience, shows that the wear in the cylinders is less than with the earlier rings, whose outward pressure was given entirely by springs. With rings which practically do not wear at all, and which are bound to keep tight whether they wear or not, it is not surprising that the economy of the engine increases with use.

14. *Drainage* (*b*).—The best-drained double-acting engines are probably horizontal engines, with separate Corliss or similar exhaust valves *beneath the cylinder.* The water lying on or draining down towards the cylinder bottom is pushed along by the piston until it reaches the exhaust port, but, unfortunately, only just before the moment of closing; however, it fills the port, and lies in it until the exhaust opens again—ready, it is to be feared, to rob the incoming steam of some of its heat during the next admission, and so to increase initial condensation. In vertical engines, at the bottom end of the cylinder the drainage may act continuously, so far as gravity can effect it, during the whole exhaust stroke, but at the upper end the water will rest on, and be carried up by, the piston until it rises above the port, when, as in the horizontal engine, only a very brief time is available for it to run away; much water probably lies permanently upon the piston, with injurious results from the point of view of initial condensation. If the exhaust port is also the admission port, the water cannot even lie there until the next exhaust; it is thrown back into the cylinder by the incoming steam. In none of these cases is the drainage satisfactory.

15. The drainage arrangements in the Willans central-valve engine offer a striking contrast to the foregoing (*see* Fig. 1). The piston is dished downwards in the centre, not so much with the idea that the water lying on the piston will drain into the centre by itself, but to utilise the inertia of the water to drive it towards the centre during the rapid up-stroke of the piston. There is a ring of ports, H H, in the trunk or hollow piston-rod, flush with the surface of the piston, and of course moving with it, and *during the whole*

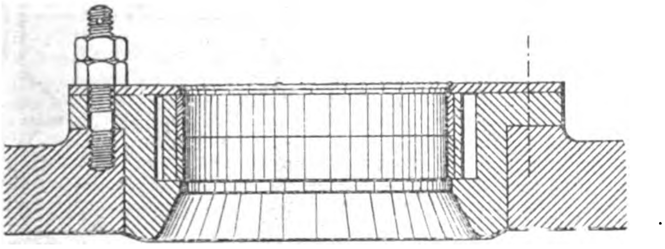

Fig. 4.—Sectional view of a steam gland box.

exhaust stroke there is a rush of steam from the sides towards these ports in the centre, sweeping over the face of the piston and assisting the action last referred to. In fact, the exhaust port is *always* in the best possible place for drainage; it is as though the exhaust port in the horizontal Corliss engine moved along the cylinder bottom so as to be always just ahead of the piston. The water is out of the cylinder before the port closes, nor is there any clearance space in the port—that is, between the cylinder and the valve—where it could lie; there is practically no clearance. It is an ideal exhaust arrangement, and there is no apparent possibility of applying either it, or anything else as good, to a double-acting engine. It is probable that it involves a saving of about 15 per cent. in the steam consumption, in comparison with other vertical engines in which ordinary slide or piston valves are used, common to admission and exhaust. In Fig. 1 the central valve L is shown in its relatively highest position; the exhaust steam (and water) are passing away into the space B, as shown by the arrows, through the ports H H and K K. B is, of course, the receiver; it is in one sense the exhaust chamber of the working cylinder A, in another sense the steam chest of the succeeding cylinder, if there be one. It will be understood that when the valve L is *below* the ports H H, steam passes into the cylinder from the upper part of the hollow piston rod.

16. *The "Cornish Cycle."*—In the Cornish single-acting pumping engine the steam acts only on the top of the piston, the space below being at the time in communication with the condensor. To develop the power of the engine, it would only be necessary to open communication during the up-stroke between the upper end of the cylinder and the condenser, and to maintain communication permanently between the lower end and the condenser; the piston would ascend *in equilibrio*, with vacuum on both sides of it. Viewing the upper end of the cylinder by itself, this is exactly what takes place in every ordinary double-acting engine, and the whole arrangement described, including permanent vacuum below the piston, is the most obvious and natural arrangement for a single-acting engine. In Watt's Cornish engine there is, however, another valve which cuts off the space below the piston from the condenser, at the moment when the steam above the piston commences to exhaust, and the exhaust takes place from above the piston into the space below it, and not direct to the condenser; the piston still ascends *in equilibrio*, but with higher pressure steam on each side of it. By this system Watt raised his pumping engine to a pitch of excellence never attained by his later double-acting engines; in fact, so economical (for a simple engine) is the old Cornish engine that in the controversies attending the introduction of the modern compound engine, the former was quoted to show that a simple engine could work as economically as a compound. The claim was excessive, except at very low pressures, but neither side realised that the Cornish engine is *not* a simple engine—it is half-way to a compound. Fig. 5 is a theoretical diagram from a simple engine in which the working cylinder opens alternately to the boiler and to the condenser. If it is also single-acting, and advantage is taken of that fact to introduce the Cornish cycle, the two diagrams given in Fig. 6 are obtained from the two ends of the cylinder, instead of the single diagram in Fig. 5. There is the same expansion in a single

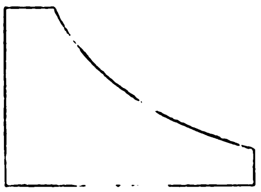

Fig 5.

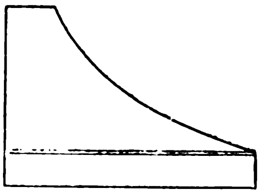

Fig. 6.

cylinder, but the range of temperature in it is only from admission temperature to release temperature, and not to condenser temperature. In other words, though the expansion is in one stage, the fall in temperature is divided over two: hence a great reduction in initial condensation, and marked economy.

17. It is obvious that with modern pressures it would be better to compound the engine—to give it one smaller cylinder and one larger, and add to the diagram the piece shown in dotted lines in Fig. 7, while making the division of temperatures more equal, as is also shown in Fig. 7. But whether the engine be simple, compound, or triple-expansion, if it is single-acting there will always be one cylinder, viz., the last of the series, to which the Cornish cycle may be applied. Mr. Willans applied it in his engine when circumstances were favourable, and he called it the "transfer plan." The steam, when it exhausts through the central valve from the upper to the lower part of the low-pressure cylinder, does not pass away at once to the condenser; it remains in the cylinder (offering no material opposition to the movement of the piston, because the two sides of the piston are in free communication), and passes to the condenser *during the succeeding down-stroke.* It adds to the engine another stage of temperature division, though not of large range, and so lessens the range in each of the others.

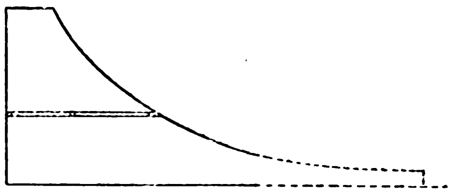

Fig. 7.

18. Simple as it sounds, the "transfer" adds several parts to the engine. The cylinders are lifted a good deal, as a "transfer chamber" is required below the low-pressure cylinder; the trunks or hollow piston rods are lengthened, and an extra valve and an extra gland are required in each line, and of course involve extra friction. Thus it is only under particular conditions of pressure, &c., that it is worth while to use the "transfer"; it is often better to add another complete stage of expansion rather than the transfer. It is, nevertheless, useful in cases where, for some extraneous reason, such as very great fluctuation of load, it is convenient to cut down the number of stages of expansion, as in an engine for electrical railway work. In such an engine the average load is usually but a small proportion of the extreme load, and the total cylinder volume should be so chosen as to give the best ratio of expansion, and therefore the most economical consumption, at the average load. It might then be impossible, without much complication, to obtain the extreme load at all, if the first cylinder were relatively so small as that of a triple-expansion engine must be, and if the cut-off in it, for normal load, were as late as in a triple-expansion engine it ought to be; it is better, therefore, to use a compound engine, gaining the needful expansion by cutting off

Digitized by Google

early for average loads, and of course cutting off late (economically, too late) for extreme loads. Economy suffers from this, but it can be partly restored by adding another temperature-division stage in the shape of the "transfer." Where the steam pressure exceeds 160lb. it is also worth while to add the "transfer" to a triple-expansion engine; it takes it half way towards quadruple expansion, the latter not being, in a Willans engine, worth the complication it introduces, until the pressure is well over 200lb.

19. It will be noticed that the last statement is qualified by the words "in a Willans engine," and by this is meant that the Willans engine, even if the "transfer" is not used, has always one definite source of superiority over other engines working with the same number of expansion-stages (*i.e.*, compound or triple), namely, in respect of the smallness of its temperature-range in each cylinder. The explanation is that, in all the expansion stages except the last one, *i.e.*, in the high-pressure and intermediate stages, the Willans engine works necessarily upon the Cornish cycle; the "transfer" is applied in those stages as a matter of course. In double-acting engines, the exhaust steam passes direct from one cylinder to the next, placing the two in communication through the receiver, and therefore exposing the first of the two to the same temperature as the second; in the Willans engine, each cylinder exhausts successively in the Cornish manner, and the power developed in each is represented, as in the Cornish engine, by two diagrams, that from the cylinder proper and that from the "receiver." The effect is that the temperatures of the high-pressure and intermediate cylinder, for instance, do not overlap, as in other engines they do, and the range in each is consequently smaller. It is perhaps the most distinctive feature in the Willans engine; it is highly advantageous to it; and it is of interest as a meeting point between the very oldest and the very newest, and as bringing together in significant association the names of James Watt and Peter Willans—an association which to the author has always appeared natural, and which he believes will at no distant time be so recognised by all.

(To be continued.)

PARLIAMENTARY INTELLIGENCE.

SELECT COMMITTEE ON THE TELEPHONE SERVICE.

The Committee met again on Tuesday, Mr. Arnold Morley, Postmaster-General, in the chair.

Major-Gen. WEBBER, R.E., C.B., called and examined by Dr. Cameron, stated that he was formerly divisional engineer of the military postal telegraphs, and was in charge of the telegraph wires during the Egyptian War. Since his retirement from active service he had been Managing Director of the Bell-Edison Telephone Company, and consulting engineer to other companies. He was well acquainted with the history of the telephone industry in the United Kingdom and on the Continent. Asked if he was in favour of a Government monopoly of telephones if there was to be a monopoly,

WITNESS replied: Not altogether. I think that the Post Office are unquestionably right in regarding the telephone service of this country as the handmaid of the telegraph service for which they are responsible, and for which the public has paid so large an amount, but my view of the possible extension of the use of telephones in this country makes me think that it will get beyond the reach of even so great a department as the Post Office. I think the latter are right in retaining the great arteries of the system, and in believing that they can manage better than anyone else that part of the system which is centrally used for commercial purposes, but the subsidiary requirements of the country will eventually require an extension of wires and stations beyond conception; and with regard to that great system of capillaries, which I firmly believe will come into existence in this country in future, I do think that it would be beyond the powers of even so great a department as the Post Office to deal with it. Therefore it would be wise for them to leave that entirely in the hands of private enterprise, securing the department against loss by means of a system of royalties.

Replying to further questions, WITNESS said he considered that since 1880 there had been two forces operating to prevent the development of telephony in this country. One was the natural precautions taken by the Post Office; the other retarding force had been the existence of a monopoly.

Dr. CAMERON: What is your idea as to the existing arrangements for telephone service in London?

WITNESS: In 1880 I was so impressed with the injury that would arise to the telephony of the future if London were not mapped out for the purpose that I was led to draw up a plan of my own. I can only say that ever since then the telephones of London have been extended in what may be called a haphazard manner. In my view each exchange should be kept for the service of the area for which it was established, instead of having its wires irregularly extended for from a quarter of a mile in one direction to three miles in another direction beyond the limits of the original area, with the view of reaching new customers. Such a system must lead to confusion, because you have a huge number of subscribers brought together at the same points, most of whom have no desire to communicate with each other, and consequently there are difficulties and delays in dealing with them. Instead of selecting a clear *clientèle* for each exchange, the effort has been to bring everyone within the 637 square miles the National Telephone Company claim to cover into intercommunication.

Asked as to what principle he would himself proceed on, WITNESS said he would first take the case of the City of London. He told the late Duke of Marlborough that to place wires underground in the City was probably one of the most difficult operations in the world, owing to the limited space available. He also told him that one great central exchange for the City was impracticable because of the impossibility of laying down, radiating from one centre, a sufficient number of cables to carry the service that would be required. He, therefore, proposed to the Duke to establish eight telephone exchanges situated at points in the periphery of the City. When the Duke suggested that eight points were not so good as one he explained to him, that there was no practical difference between having eight exchanges at eight points in the City and having eight exchanges in eight rooms in a single house. The Duke saw the force of the argument, and induced the City of London Electric Lighting Company, in laying down their system for the distribution of electric light, to insert in all their trenches extra or spare tubes in sufficient quantity to meet the possible future demand for telephone purposes. The Duke also entered into agreements with other electric lighting companies in the City to do the same. He denied that there was anything surreptitious or underhanded in the laying down of those spare tubes; it was open to anyone to see what was being done. Of course, the City of London Electric Lighting Company could not positively say that the spare tubes were destined to be used for telephones, but there was no doubt that the Duke of Marlborough, in getting the electric lighting companies to lay them down, had a very strong view that they might be used for the purposes of the New Telephone Company, of which, as well as of the City of London Electric Lighting Company, he was a Director.

By Mr. Benn: By means of these tubes his system of eight exchanges could have been carried out without the abomination of overhead wires. There was no reason to-day why that should not be done if those tubes were available. The length of 2½in. tubing was 147 miles, and they were capable of holding 12,500 miles of twin conductors. The City of London Company expended £69,000 on the tubes, and the cost of the twin wires necessary for his scheme would be £80,850 when drawn into the tubes, making a total of £149,850, or £1,020 per mile.

WITNESS went at some length into figures, with a view of showing the financial practicability and advantages of his plan.

In answer to Dr. Cameron, WITNESS said he claimed that his system of limited exchanges supplemented by a system of tolls chargeable to persons using exchanges to which they were not subscribers would enable them not only to satisfy the large cities and towns, but also to meet the wants of small traders, farmers, and other persons in rural districts. He had been a member of the Board of Trade Committee on Light Railways, but it struck him that if the object was to benefit agriculture the establishment of a rural telephone system should have consideration before the construction of light railways.

By the Chairman: Under his scheme for London a subscriber would practically pay £8 a year to be in communication with one-eighth of the City. If he wanted to go beyond that he would have to come under a separate classification or toll which would have to be a matter of calculation and arrangement.

By Mr. Grant Lawson: Witness had never been consulted by the National Telephone Company, He could not admit that under his system the officials at the call offices would be put to the trouble of ascertaining the number of the subscribers to be communicated with at a distant exchange. A person in London wishing to call some one in Manchester would have to supply the latter's number just as he had now to supply his address if he wanted to write or wire him. The public would soon adapt themselves to such a requirement. In regard to his rural scheme, if it was undertaken by the County Councils and if the revenue did not come up to witness's estimate no doubt the deficiency would have to come out of the rates.

In answer to Sir J. Fergusson, WITNESS admitted that if private companies or municipal authorities succeeded in obtaining licences from the Post Office they would, in view of the fact that all such licences would lapse to the Postmaster-General in 1911, have to face the necessity of providing a sinking fund for 16 years.

By the Chairman: He was in favour of the State taking over the whole telephone system of the country, except in the rural districts. In regard to his proposals respecting the City, he knew of no town in any country which had adopted such a system, but then it must be remembered that there was no town like London.

The CHAIRMAN: You not only differ from the National Telephone Company in the plan they have adopted, but also from every country in the world in the plans they have adopted?

WITNESS. I don't know whether the Americans have laid out their plans with a view to the future of New York, or the French with a view to the future of Paris.

In answer to further questions, WITNESS said in his rural scheme he proposed to have no subscribers; everything would be done by a payment of 2d. per call, for a conversation of five minutes. He had allowed 3s. 6d. per week for expenses of each call office. He had made no provision for a silent box. The chance of being overheard was an inherent defect of all telephonic communication.

General Webber's evidence having occupied the Committee for nearly four hours, the examination of Sir F. Bramwell and Mr. J. S. Forbes, who had been in attendance throughout the sitting, was postponed until to-day (Friday).

CORRESPONDENCE.

FIRE RULES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: As certain statements have been made with regard to electrical installations placed up in consumers' premises that may give rise to erroneous impressions and cause needless alarm, I beg you will be courteous enough to spare me a portion of the valuable space in your columns to enable me to say a few words upon the subject.

So far from electrical installations being now placed up in buildings in a worse manner than formerly, my experience is that every year shows an improvement in the way the work is done; and that taking electrical installations as a whole the work is better put up now than it has ever been. So far as I can learn there is no country in the world where the installations inside buildings are to be compared to those installed in England.

With regard to fire danger I have to say that the Phœnix Fire Office has not yet had to pay a shilling of loss with regard to any electrical installation of any kind, when the work has been placed up in accordance with its rules, notwithstanding the enormous number of buildings containing electrical installations that have come before that Office, comprising not only private houses, but all kinds of public buildings, mills, factories, workshops, warehouses, shops, &c., &c. And this immunity from loss has not merely been for a year or two, but extends back to the commencement of electric lighting in the beginning of 1882—over thirteen years ago. A more satisfactory condition of things, from a fire point of view, it would be impossible to conceive.

It is with great surprise I learn that the Institution of Electrical Engineers is about to issue new rules for electrical installations inside buildings. I have to state that the Phœnix Fire Office will not for one moment recognise any such rules if they be issued; and it is well that all electrical contractors, not only in London, but throughout the country, should be fully aware of this. The Phœnix Fire Office will not depart from the course that long experience has proved to be so safe, and will require as before that in any building insured with it the electrical work shall comply with its rules. It has the responsibility of paying for fire losses, and therefore it is absurd to think that it would agree to anything that might practically place the disposal of its funds at the mercy of the views of an outside body.—Yours, &c., MUSGRAVE HEAPHY.

London, May 16, 1895.

SERIES GLOW LAMP LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In the article on the "Parfitt Series System" in your issue of the 10th inst., it is stated that "we think it to be a fact that as yet no other device has been used for this purpose with even a fair degree of success." In this connection, I would beg to say that several stations in the States and elsewhere, chiefly small towns, are using, and have been for several years, the Thomson-Houston series alternating system for street lighting with every success. The cut-out used is very simple, reliable, and inexpensive. In one station I was personally acquainted with, four circuits of 40 25-c.p. lamps each have been running for more than two years without any trouble.—Yours, &c., ARTHUR H. SHAW.

Holly Bank, Cornbrook, Manchester, May 14, 1895.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your last week's issue, when describing the Parfitt system of electric lighting, you say "It is well-known that incandescent lighting by series lamps has not been successful, at any rate in any place in Great Britain," and then you go on to say, "The difficulties have been twofold: first, the candle-power provided has generally been too small, and secondly, the failure of a lamp filament has been apt to open the circuit, in spite of automatic devices, and to put out all the lamps in the series. In the experiment made at Barnet a few years ago, both of these causes operated to condemn the series system."

We beg to say your criticism of the Barnet lighting is quite erroneous; neither of the causes you mention applied to Barnet. We used 32-c.p., 50-c.p. and 100-c.p. incandescent lamps and 1,000-c.p. arc lamps at Barnet, so that it cannot be said that the candle-power was too small, and in no single instance did the automatic device fail to act. We had trouble at Barnet: our posts were knocked down by carts, as we understand was the case at Kingswood, but the whole of the failures at Barnet from first to last, including single lamps not quickly replaced during our three years of contract lighting, did not amount to more than ½ per cent. We say that such a result was a very great success.

The reason why the Barnet lighting was not continued, and why we obtained £500 damages from the Local Board for breach of contract, are quite outside the question as to the success and value of the system of incandescent series lamps for street lighting we introduced for the first time in this country at Barnet.—Yours, &c.,

May 15, 1895. HENRY F. JOEL & Co.

[We are quite ready to accept Messrs. Joel's statement that none of the Barnet failures were due to their automatic bridge, and we regret therefore that we cast any reflection on its efficacy. But the fact remains that the public lighting of Barnet was by no means a good advertisement for electric lighting; that the lamps were frequently extinguished; that whatever the photometer candle-power might have been the light was distinctly disappointing, and from first to last there was constant strife been the Local Authority and the contractors; all of which, we hold, can be traced to the adoption of glow lamps for street lighting, and was aggravated by the fact, that being in series, the vagaries of a single erratic coster's cart was sufficient to cause a big interruption.—ED. *E.*]

"EARTHING."

TO THE EDITOR OF THE ELECTRICIAN.

Sir: With reference to the report and leader you publish in your issue of April 26th, referred to by Mr. Sharpe, probably the reason for the lack of publication you refer to is due to the limited experience that has been gained *re* earthing street mains in this country, and also to the definite regulations set out by the Board of Trade, which have given an appearance of settlement to the question.

The report you publish and the authoritative names attached to it should, and it is to be hoped will, induce those responsible for such regulations to reconsider the restrictions to earthing, and provide rules to admit of and regulate earthed systems.

The Board of Trade regulations as they stand limit the choice of the consumer to practically one system in the houses, the two-wire, and prevent the selection of the earthed concentric system, which has conspicuous benefits in price, safety, and neatness. Is not such a restriction opposed to the principles of the Board of Trade? If so, it is an additional reason why a modification of the regulations should be expected.

The report you publish relates solely to the three-wire system; but the advantages recited are even greater when the two-wire system is earthed, whether continuous or alternating currents be used.

If the influence on telegraphs and telephones is entirely due to wandering currents, or in any case it will be less if one of the conductors be earthed under correct conditions, for the reason, as stated in the report, that the distance traversed by wandering currents is reduced, in fact, it is practically reduced to the distance between the two parallel wires; and if an earthed concentric conductor constitutes the mains, there will be no current at all passing through earth from one conductor to the other.

The following are the main conditions under which street mains may be earthed:—The feeders to the network should be insulated at the dynamo end, and throughout their length to the feeding point. The earthed conductor of the network should be uninterrupted by fuses or switches throughout. With continuous currents the negative would be the earthed conductor, and it should be insulated to a light degree to provide

Digitized by Google

against electrolysis, but be earthed at each feeding point and house connection. If alternating currents are used, the insulation on the earthed conductor is not a necessity. If concentric cables are used, the earth connections may be omitted. To reduce as far as possible the pressure between different points of the earthed conductor, the extreme ends of branches should be connected together and where possible back on to the mains. A further saving in fall of pressure may be effected by putting the extra metal that would be added to both conductors above the normal capacity all into the earthed conductor; this would specially refer to continuous currents and a two-wire or concentric system.

An earthed concentric system for street mains has special advantages as an earthed system, whether for double or three wires, and the service joints are exceedingly cheap to make. Notwithstanding an earthed street system, it will be understood that both wires in the houses should be well insulated, except with concentric, and the switches and fuses would be inserted in the non-earthed conductor only.

The writer has had sufficient experience both with earthed street mains and earthed interior wiring, concentric and two-wire, to be able to assert that telephones and telegraphs interference is at least no greater with a properly arranged earthed system, whether for continuous or alternating currents, and the same may be said with regard to electrolysis.—Yours, &c.,

J. D. F. ANDREWS.

45, Fulham Park-gardens, S.W., May 14, 1895.

CURIOUS VACUUM TUBE PHENOMENA.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With regard to the behaviour of a vacuum tube, as cited by your correspondent, Mr. W. Lomas, in May 10th issue, I have often noticed the after-glowing in question, but cannot say I have ever regarded the explanation as very obscure. The same explanation of course holds for the shocks obtainable from a tube. Both are due to the discharge of accumulated electrostatic strain in the glass.

The following experiment, in which a clean, dry glass plate without conducting coatings is charged in a similar manner, may make clear the actions taking place which give the effects spoken of. The knobs of a Wimshurst machine, preferably minus the jars, are placed so that on turning a continuous discharge is kept up from knob to knob. In the path of the discharge insert the glass plate. The discharge still continues vigorously for a time on either side until the plate is fully charged. Proof of this charged state can then be had by laying the glass flat on a smaller piece of insulated tinfoil, and placing a similar piece of foil on the upper surface, in which case the glass and foil simply constitute a charged Franklin's pane, from which shocks or the usual Leyden jar discharge can be obtained.

In the vacuum tube the electrostatic capacity producing the effects is not at all inconsiderable on account of the amount of surface and thinness of the glass. On presenting the tube to the machine to obtain a glow, the fingers or hand (and the effect is increased if the tube be completely grasped by its centre in the hand) represent a conducting coating already on one side of the glass, and it is not even necessary that the tube should be exhausted in order to charge the glass from the inside. The exhaustion is necessary, however, to obtain a shock from the tube, as the inner surface is, of course, more readily discharged through rarefied gas. The after-glowing is due to the gradual discharging of the tube as the outside charge creeps over the surface to the electrodes.—Yours, &c,

Postal Telegraphs Instrument Factory, J. E. TAYLOR.
Holloway, N., May 13, 1895.

ACCIDENT AT CHELMSFORD.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: An accident occurred to one of our men in connection with the electric lighting of this town, and as we notice that an erroneous description of the causes which led to the accident has found its way into the papers, we beg to give you what we believe to be the true facts of the case, so far as we have been able to ascertain them.

Our man went up a ladder placed against a pole in order to fix some new insulators for a new circuit. He hooked a linesman's vice on to the steel suspending wire of the street lighting circuit, which was then switched off. This steel wire was probably charged by induction from the neighbouring private lighting circuit, so that when our man placed his hand upon it, and touched the lightning conductor or transformer case, which was connected to the earth, he received what is called a static shock, harmless in itself, but which probably caused him to lose his balance. He fell 20ft., and has received serious injuries, which are, we believe, entirely due to his fall, and not in any way connected with the static shock, but we hope he will make satisfactory recovery.—Yours, &c, A. H. POTT.

Arc Works, Chelmsford, May 14, 1895.

PROF. FORBES'S ROYAL INSTITUTION LECTURES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In attributing to me the particular modification of Lord Armstrong's cotton thread experiment shown by Prof. Forbes at the Royal Institution last Tuesday, I fear you are giving me credit to which I am altogether unentitled.

The experiment was shown at the Royal Institution in precisely the same form as that in which Lord Armstrong himself exhibited it to the Literary and Philosophical Society, Newcastle-on-Tyne, in February, 1893.—Yours, &c.,

May 10, 1895. A. A. C. SWINTON.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May 3, 1895.*

General Electric Company's Annual Report.—The third annual report of the General Electric Company was made public on Wednesday, and while it shows that a profitable business was done during 1894, but little improvement in the position of the Company is indicated. The sales for the year 1894 aggregated $12,540,395, and receipts from other sources brought the total up to $13,263,611. The gross profits were $1,811,747, against which are the following charges: Interest on debentures, $464,583; various old losses between 1894 and earlier years, $443,023; cost of patents and franchises acquired during the year, $162,293; depreciation of inventions, $288,401; sundry losses, $38,798; leaving a net profit of $414,642. Notwithstanding the fact of the expiration of three of the most important patents of the Company during the last year —the incandescent lamp, feeder-and-main and Thomson arc regulator patent—that asset is yet carried at $8,159,264, which is the same as appears on the first annual report of the Company made three years ago. Among the losses noted are $945,000 through the failure of the North-West General Electric Company, and an asset added consists of a claim of $1,137,555 against the Fort Wayne Company, now in the hands of a receiver; in connection with the latter item it may be stated that in last year's report the stock and bonds of this Company, held by the General Electric, were scaled by the latter to $1.00 from over a million. This year's statement shows that the debt of the Company, other than outstanding debentures and real estate liens, has been reduced from $2,022,454 to $90,021, but, on the other hand, the profit and loss balance, or shrinkage of assets, is raised from $12,454,967 to $14,794,716.

Niagara Power for Buffalo.—The Committee of the Buffalo Council charged with specifying the terms of a franchise permitting the Niagara Company to sell electric power in Buffalo, after unusually lengthy deliberation, handed in its report on Saturday of last week. In brief, it is proposed to grant a franchise for 25 years, at the expiration of which time the City may purchase the plant at appraisal, on one year's notice of its intention to purchase, and if such notice is not given, the grant is to be renewed for another 25 years or longer term, subject to such conditions as the Council may impose. A bond for $250,000 is called for. The grant is not to be transferable or

Digitized by Google

assignable without the Council's consent, and there is a provision against consolidating or merging with any other company to prevent competition or reduction in price. The grant provides that accommodations shall be afforded on poles or in conduits for at least two other companies requiring the same facilities as the Niagara Company, which extra space may be used by the City for public purposes without charge. Free accommodation is to be provided for fire alarm and police wires, and the Company will be required to supply the city with power to run the waterworks or for other public purposes at not exceeding $20 per horse-power per annum for use 24 hours in the day, and to light the streets at a cost not to exceed $50 a year for each electric light of 2,000 c.p. It is also provided that any contractor may have electricity at the city line for street lighting at the same figure. When applications aggregating 1,000 H.P. come from within a radius of a mile from any part of the city where the company has not constructed a line of transmission, and the applicants tender contracts for at least one year, accompanied by a satisfactory bond, the Company may be ordered by the Common Council to extend its line of transmission within six months so as to comply with these demands. The Company must be prepared to supply 10,000 H.P. to consumers before December 31, 1895, and 10,000 additional every year thereafter for four years in accordance with the demand. The general plan is to be under the direction of the Council, the details under the superintendence of the Board of Public Works. No price is specified for the cost of supply to private consumers, but one consumer cannot be charged more for the same or less quantity of electricity than another, or more than the Company will charge other persons further from its Niagara generating station.

LEGAL INTELLIGENCE.

Muirhead and Others v. the Commercial Cable Company.

The defendants' appeal in the case of Muirhead and Others v. the Commercial Cable Company was in the list on Tuesday last for hearing in the House of Lords. It will be remembered that the action, which has reference to a patent for the duplex working of submarine cables, was tried in March, 1894, before Mr. Justice Kennedy, who gave judgment for the plaintiffs, a decision which was reversed on appeal in December last.

Counsel for the plaintiffs: Mr. Finlay, Q.C., Mr. Bousfield, Q.C., M.P., and Mr. E. H. Pollard; for the defendants: Sir Richard Webster, Q.C., M.P., Mr. Moulton, Q.C., M.P., and Mr. Walter. On the case being called, Mr. Finlay, Q.C., for the plaintiffs, stated that their lordships would not be asked to adjudicate in the matter, which had been settled by the parties on terms which did not transpire; but we understand that the plaintiffs have succeeded in their claim, and that a considerable sum has been paid to Messrs. Muirhead for royalty.

Crossley Brothers (Limited) v. Peel and Others.

On Monday last, in the House of Lords, an appeal of considerable importance to engine and machinery builders was decided. It was an action in which Messrs. Crossley Brothers (Limited), the well-known gas engine makers, resisted the contention of the official assignees of the Court of Bankruptcy in Ireland as to the legal construction to be placed upon an ordinary hire-purchase agreement. The bankrupt, T. F. Peel, had obtained from Messrs. Crossley Brothers a gas engine which he agreed to pay for by instalments, the agreement expressly stipulating that until the payment of the £240 by instalments had been completed the engine was to remain the property of Messrs. Crossley Brothers, who were empowered on the failure to pay any of the instalments either to sue for the unpaid balance, or to demand the return of the engine. Only £60 was so paid, and after the bankruptcy of the hirer, Messrs. Crossley Brothers demanded the engine to be returned, but the official assignees in bankruptcy disputed the firm's right, and they succeeded in obtaining a verdict to this effect in the Irish Bankruptcy Court. The Irish Court of Appeal, however, set aside this verdict, and the assignees then appealed to the House of Lords, with the result that the judgment of the Irish Court of Appeal was upheld with costs, the Lord Chancellor stating that it was a very plain case of an agreement between the parties which must be construed precisely as though no bankruptcy proceedings had taken place and apart from any statutory provisions. The parties to it had in terms expressed their intention that the property in the engine should not pass until the instalments were paid. He knew no reason why such an agreement should be regarded as an illegal one.

H. Binko and Co. v. Leslie.

This case was heard in the City of London Court, on the 13th inst., by Mr. Commissioner Kerr. It was a claim by the plaintiffs, of Leadenhall-street, for £2. 10s. for goods supplied to the defendant, as the receiver of Woodhouse and Rawson United (Limited). The defendant's solicitor said the goods were supplied neither to Woodhouse and Rawson nor to the defendant, but to one Long, who gave the order on his own behalf. Long would have paid for them but for a dispute. The plaintiffs' case was that the goods were received by Woodhouse and Rawson, one of whose boys signed for them. It was said that the boy had no authority to sign for them on behalf of the firm, but the learned Commissioner found for the plaintiffs, with costs.

Carter, Saunders and Co. v. Rummens.

Mrs. Elizabeth Rummens, of 48, Leadenhall-street, E.C., was sued in the City of London Court by the plaintiffs, of Great Turnstile, High Holborn, London, W.C., for £4. 19s., the price of telephones supplied, as alleged, to her. It seemed that the telephones were supplied by the plaintiffs on sale or return, and that after a time they stipulated a date on which the goods were to be returned, or else to be considered as sold. The defence was that the telephones were supplied to the defendant's son, and not to the defendant's order at all. Mr. Commissioner Kerr found for the defendant, but disallowed her costs.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Although about 100 pages are added to the book, no addition is made to the price, which is 7s. 6d., post free 8s. 3d., abroad 9s.

The following New Books and Editions of "THE ELECTRICIAN" SERIES *can be obtained of the Booksellers or direct from the Publishing Offices:—*

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. A full prospectus can be obtained post free.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

A LARGE-SHEET TABLE, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 3s. 6d.; Unvarnished, 3s. —each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell, with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains some 230 illustrations, a large proportion of which have been specially made for the book. The price is 10s. 6d. post free (abroad 11s.).

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

"ELECTRO-CHEMISTRY."—This useful work, by Dr. G. Gore, is still on sale, the price being 2s., post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. net., is now ready.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ELECTRICIAN."—A special notice concerning certain changes in the price, &c., of this journal will be found on page 86.

TENDERS INVITED.—The Corporation of Birkenhead invite tenders for the supply and erection of apparatus and plant for their electric supply works. Tenders must be in by 12 noon of the 23rd inst.

Digitized by Google

TENDERS INVITED.—The Electric Lighting Committee of the Huddersfield Town Council invite tenders for cables, transformers, switches, fuses, and covers for their electric lighting works during the ensuing 12 months. Specifications and particulars can be obtained of Mr. A. B. Mountain, borough electrical engineer, St. Andrew's-road, Huddersfield, and tenders have to be sent in to Mr. Mountain not later than Saturday, June 1st. Some particulars are given in our advertisement columns.

——— The Corporation of Hanley invite tenders for the supply, delivery, and erection complete of boilers and fittings, water tank and girders, arc lamps, of cables, street boxes, &c., transformers, switches, &c., under contracts Nos. 12, 13, 14, 15, and 16. Forms of tender, specification, &c., can be obtained at the Town Hall, Hanley, Staffs , and tenders have to be sent in to Mr. Joseph Lobley, borough engineer and surveyor, before Monday, the 27th inst. Some further particulars are given in our advertisement columns.

——— The Corporation of Brighton invite tenders for—(a) Preparation, supply and delivery at Brighton of cast-iron lamp pillars and copper canopies ; (b) Preparation, supply and delivery of cast-iron and drawn steel bracket posts, for which tenders must be sent in before 10 a.m. on Monday, May 27th. Drawings, &c., may be had from the offices of the borough engineer and surveyor, at the Town Hall, Brighton. Some further details will be found in our advertisement columns.

——— The Electric Light Committee of the Oldham Corporation invite tenders for two 200-H.P. steam engines and dynamos and steam pipes. Specifications, &c., can be obtained from Mr. A. Andrew, at the Gas and Water Offices, Oldham, and tenders must be sent in to Mr. Andrew not later than Tuesday, May 28th. Some particulars are given in our advertisement pages.

——— Tenders are being invited until June 29th by the Municipal Authorities of Brailă, Roumania, for the concession for the lighting of the public streets either by electricity or gas.

——— Tenders are invited for the construction of foundations for new engineering works at Rugby for Messrs. Willans and Robinson (Limited). Plans, &c., can be obtained of Mr. T. W. Willard, architect, St. Andrew's Chambers, Rugby, and tenders, addressed to the secretary of the Company, Mr. C. S. Essex, Picton House, Thames Ditton, Surrey, must be in by the 30th inst.

——— Tenders are required for the installation of an electric lighting plant at Elswick Lead Works, Newcastle-on-Tyne, for Messrs. Walkers, Parker and Co. (Limited). Tenders to be in by May 16th.

TENDERS ACCEPTED.—The tender of Messrs. Rogers and Co. has been accepted by the Hampstead Vestry for the construction of transformers and draw-boxes, for the sum of £57 for each large transformer chamber, £49 for each small chamber, and £3 for each draw-box.

——— The Huddersfield Borough Council have accepted the tender of Messrs. S. Z. de Ferranti (Limited) for plant required at the electricity supply station, for the sum of £3,558.

——— The Londonderry Town Council have accepted the tender of Messrs. Siemens Brothers and Co. for the supply of arc light carbons.

——— The Bolton Corporation have accepted the tender of Messrs. Hick, Hargreaves and Co. for an additional engine for their electricity works.

SALE BY AUCTION.—Messrs. Wheatley Kirk, Price and Goulty will sell by auction at the works of the Leeds Machinery Stores Company, Kirkstall-road, Leeds, *on Tuesday and Wednesday next*, the entire stock of new and second-hand machinery detailed in our advertisement columns. Particular attention is called by the auctioneers to the large number of valuable machines to be disposed of. Further particulars and catalogues can be obtained at the stores, Kirkstall-road, Leeds, or of the auctioneers, 49, Queen Victoria-street, London, E.C., and Albert-chambers, Albert-square, Manchester.

APPOINTMENTS VACANT.—The Governors of the Woolwich Polytechnic invite applications for the following appointments :—(1) Principal of the Polytechnic, (2) Head of Social and Recreative Department, (3) Clerk to the Governors. Some particulars are given in our advertisement columns, and all further information can be obtained with forms of application from the office of Mr. W. Garnett, the hon. secretary, 13, Spring-gardens, S.W. Applications have to be in by 10 a.m. of May 25th.

——— The Tunbridge Wells Town Council require a resident engineer for their electricity works. Salary, £250 per annum. Applications have to be in by the 25th inst.

APPOINTMENT.—The Hampstead Vestry, having considered the qualifications of the six gentlemen mentioned in our last issue at its meeting last week, finally selected Mr. G. H. Cottam, of Hanley, who obtained 34 votes, against 26 received by Mr. E. Sayer, of Hampstead. Mr. Cottam, who is 44 years of age and a member of the Institution, has for some time past been chief electrical engineer to the Hanley Corporation Electric Lighting Works, and has had a very varied experience in engineering and electrical work. The commencing salary at Hampstead is £300 per annum. Mr. Sayer has been appointed to take charge of the station until Mr. Cottam finally takes up his duties.

DISSOLUTION OF PARTNERSHIP.—Messrs. J. S. Morris and C. C. Gold, carrying on business as electrical engineers under the style of Morris and Gold at Wardrobe-chambers, Queen Victoria-street, London, E.C , have dissolved partnership.

MESSRS. POPE, BODDY AND CO.—In order that there may be no misunderstanding as to the effect of the retirement of one of the partners (Mr. Barker), we are desired to state that there is no alteration whatever in the business of this firm, but that everything will continue as hitherto. Messrs. Pope, Boddy and Co. report that the sale of their incandescent lamps has rapidly increased, and that they have a good demand throughout the country. Mr. Pope, who was one of the first to engage in the incandescent lamp business in this country, has been for some time past engaged in making some improvements, which are now completed, and the patents taken out. Under these improvements plaster has been superseded, with the result that the life of the lamp has, it is stated, sensibly increased. In addition it is claimed that the material of the old lamps can be used up again, including the bulb and the old cap. A metal ring is used attached to the glass on which the cap is fastened, enabling the parts to be easily disconnected. Other claims are—1. Perfect insulation, enabling the lamps to be burnt in any atmosphere without danger of loss of current through saturation ; 2. No interruption of circuit through current passing from one pole to the other; 3. Absence of heating other than that caused by the energy expended in the lamp; 4. Owing to the absence of plaster there is less liability of the glass cracking at the leading-in wires through expansion or contraction. In *The Electrician* for November 25, 1892, a report appeared, in which, from the result of experiments made, favourable mention was made of these lamps ; and the firm claim that since that period many improvements have been adopted.

BANKRUPTCY.—The first meeting of creditors in the bankruptcy of P. C. Pope, electrical engineer, of Hapton, near Burnley, will be held at the Exchange Hotel, Burnley, on May 23rd, at 3:30 p.m. The public examination takes place at the County Court, Burnley, on the same day, at 11 a.m.

DIVIDEND.—Notice is given that a second and final dividend of 11d. in the £ is now payable in the liquidation of Newington, Priddle and Co. (Limited), at the Official Receiver's, 33, Carey-street, London, W.C., any day except Saturday.

REMOVAL.—The "Empire" Telephone Company, who are also makers of the electro-magnetic "Victory" telephone, have removed to 1, Lombard-court, 32, Gracechurch-street, London, E.C.

PERSONAL.—Mr. Richard J. Middleton, manager of the *Mining Journal*, has opened a mining agency at Broad-street House, London, E.C.

AMSTERDAM.—At an exhibition opened in this city on Saturday last, which was originally to be one of hotel equipment and travel, but which has considerably developed. In addition to a large number of exhibits showing plant in connection with the construction and equipment of railways and shipping, there are many of the latest electrical novelties, including "an electrical restaurant," where guests are served by means of electric contrivances.

ARGENTINA.—The Government at Buenos Ayres has contracted with Messrs. Bonison and Mautalen for the construction of a building for the electric light station for the illumination of the port works, at a cost of $49,450.

ASHBY-DE-LA-ZOUCH.—The Gas Committee of the Urban District Council, in recommending that the arrangements for lighting the district by gas should be renewed up to March, 1896, further recommend that the Council should take into consideration the advisability of lighting the town by electricity. The Committee's report was approved.

ASYLUM LIGHTING.—The Hartwood Lunatic Asylum, recently erected for the Lanark District Lunacy Board, and which was formally opened on Tuesday last, is lighted throughout by electricity. 1,260 lamps, from 8 c.p. to 100 c.p., are used. Besides the generating plant, storage batteries equal to the entire capacity of the lamps have been installed. The various sections of the building are being connected by telephone.

BELFAST.—In this city, as in the metropolis, the question of the telephone service is one upon which the leading business men feel keenly. In December last a severe storm interfered seriously with the working of the service, and the storm of January 13th completed the havoc. Since this time the telephone service of Belfast has left much to be desired. At the quarterly meeting of the Chamber of Commerce, last week, Mr. J. H. Greenhill brought the

Digitized by Google

matter forward, and said the telephone in a city like Belfast had become a matter of necessity, and the whole subject called for the immediate attention of the Chamber. There could be no doubt that if the telephone were properly worked it was an immense advantage to business men, but, if badly worked, was a nuisance and a hindrance to business. The Company who provided them with the telephone had received the sympathy of their subscribers owing to the heavy gale which prevailed in December last, but at the same time it was thought by many of them that after four or five months had elapsed it was time that the wires were put in working order again, as it was not difficult to see that the time would shortly come round when another storm would put them *hors de combat*, and leave the subscribers in even a worse position than before. No blame, he thought, attached to the local managers of Belfast; but he thought there was a want of vigour in the governing body. The agreement they had signed with the Telephone Company was a very stringent one, and seemed to him to show a clear want of mutuality of conditions that it was questionable if it could be sustained in a court of law. When, in addition to this, it was remembered that telephone subscribers paid in advance the onesidedness of the arrangement was apparent. He thought it a proper question for the Chamber to consider whether the Company, having received payment in advance, and having failed to render in return the services agreed upon, were entitled to the payment made. If a subscriber could call upon the Company to refund a portion of the money paid in advance for services not rendered, it would be an incentive to the Company to give more prompt attention to the requirements of their subscribers. Perhaps there was an analogous instance in the case of one of the English railway companies, where a number of passengers booked through to a certain destination, and after getting a certain distance they were impeded by a snow storm and were unable to proceed further. The railway company, after looking into the matter, found that it was necessary for them to return the fares for that part of the journey which was not completed. He was not quite sure whether the same rule would not apply to the Belfast Telephone Company.—Mr. G. McConnell supported Mr. Greenhill, and said that with regard to the agreement they must sign it or their telephone would be taken away; they must pay in advance or their telephone would be cut off; and they had to pay whether the services were rendered or not. If the Company knew that they would not be paid for any time the services were not rendered, he believed repairs would be made more quickly, and better attention would be paid to the wants of the subscribers.—Mr. Greenhill subsequently proposed "That the alleged imperfections in the working of the Belfast Telephone Company's service, as well as the stringency of the conditions imposed upon subscribers, be referred to the law committee of the Chamber to consider and report to the Council."—Mr. C. C. Connor, M.P., Chairman of the local directors of the Telephone Company, thought it was not at all unnatural that attention should be drawn to the delay in repairing the telephone system after the great storm of December last; but if they were conscious of the enormous amount of damage that had been done, and the number of wires that had been destroyed, he thought they would have more consideration for those in charge of the system. In addition, the still more serious storm on January 13th did more harm to the telephonic and telegraphic system than even the great storm of December. After the storm in January they had 480 exchange wires missing from the exchange in Belfast alone. The Company had put up 300 miles of new telephonic wires since the December storm, and were still continuing the repairs. As to who was to bear the loss of the interrupted service, it must be remembered that this was beyond all human control, involving great expense to the Telephone Company, and he thought that it was not unreasonable for the Company to ask that the subscribers should themselves bear the loss—(laughter)—that was to say, should put up with the deprivation of service. Mr. Greenhill's proposal was carried.

Belgium.—A Foreign Office despatch from Her Majesty's Minister at Brussels, dated March 27th last, contains two maps—one of the Belgium railway system and another showing postal, telegraphic, and telephonic facilities throughout the kingdom.

Bowness.—The proposed agreement between the Urban District Council and Messrs. R. H. Fell and Son for lighting this village by electricity has been approved upon the recommendation of the Lighting Committee.

Bury St. Edmunds.—The leading local firm, Messrs. Oliver and Richardson, have recently put down plant for the lighting of their business premises in Abbeygate-street by electricity, and have obtained the permission of the Local Authorities to supply current to tradesmen on the opposite side of the street, necessitating the opening of the roads. The gas interest on the Town Council were opposed to permission being given, but finally the recommendation of the Highways and Waterworks Committee granting the request was approved, subject to the conditions of the Electric Lighting Act.

Cheltenham.—At the last meeting of the Town Council, Mr. Alderman Norman presented the Electric Lighting Committee's report, which stated that the supply station had been running from April 9th, and from the start there had been no hitch or anxiety. They had begun the supply with a total equivalent of about 2,000 8 c.p. lamps wired, and he had little doubt that the Committee's anticipations would be justified and the electric light prove no burden upon the ratepayers.

Church Lighting.—The church at Buckland, near Dover, has for some time past been lighted electrically, and a letter from the vicar and churchwardens states that "after a month's trial of the electric light we consider it only right to say that the result is indeed gratifying, exceeding by far our most sanguine expectations. For the three months ended March 31st the cost of gas was £3. 18s. 3d., while with electricity, based upon the consumption during the last month, it would have been £3. 5s. 1d. For the purpose of this test the church has been lighted during April for the same number of hours as in January, and thus shows an absolute gain of 13s. 2d. per quarter. Our other substantial gains are improved ventilation, intensity of light, and cleanliness. We can strongly recommend its adoption to other churchwardens."

Colwyn Bay.—At the last meeting of the District Council it was decided to appoint a committee to take the necessary steps for obtaining a Provisional Order to enable the Council to supply the district with the electric current.

Cowes (I. W.)—Mr. Nelson F. Dennis, the town surveyor, has presented a lengthy report, including a scheme for lighting a portion of the town by electricity. Under this scheme it is proposed to first of all provide plant equivalent to 2,200 8-c.p. incandescents, with an ultimate main capacity of 3,000 lamps. Willans' engines and Cornish boilers with Meldrum's furnaces, are recommended, together with an accumulator set capable of taking the entire day load. The scheme is estimated to involve an outlay of £6,000. The annual maintenance is estimated at £1,100, and the revenue at £1,275, plus £133. 10s. per annum for public lighting. At its meeting on Tuesday evening the District Council discussed the advisability of employing an expert, but ultimately it was decided to refer the whole matter to the Water and Lighting Committee to bring up the names of several experts, and to prepare and provide other information on the subject for an early meeting of the Council.

Code Telegrams to China.—The Eastern Telegraph Company notify that they have received advice that the Chinese Government will now accept code telegrams for inland stations in China without restriction.

Crewe.—At the last meeting of the Town Council a letter from Mr. W. Wade, builder, asking the Council if they were favourable to a tramway being laid down from the corner of the gasworks to the Queen's Park, which could be worked by horses or by electricity generated from the waterfall in the Park, was referred to a committee for consideration and report.

Customs Tariffs.—Under the British Honduras tariff ordinance of 1895, included in the articles which are exempt from duty are: Plant and materials for railways, telegraphs, telephones, tramways, and electric lighting. The Legislative Council of St. Vincent, on the 14th of March last, passed an ordinance exempting machinery driven by steam, water, electricity, gas or compressed air; telegraphic wire, telegraphic, telephonic and electrical appliances of all kinds for communication or illumination, including all material required for use by the West India and Panama Telegraph Company.

Dublin Tramways.—We have received from Mr. Robert Hammond a copy of his "Report on Electric Traction in Dublin," addressed to the Directors of the Dublin United Tramways Company. This report sums up strongly in favour of the side trolley.

Exhibition.—There is to be a great national exhibition at Kioto (Japan), which is to continue open till August, 1895 (?1896). An association called the Taihina-Kyokwai has been formed with the special object of affording information and generally helping intending visitors to the exhibition, one of the chief objects of which is to introduce to Japanese specialists those who desire investigation in science, arts, and manufactures. The association is also to be a medium for business transactions between foreigners and the Japanese.

Expansion of Telegrams.—*The Times* of the 15th inst. contains a moderately worded but effective protest against what appears to be, if the facts are as stated, a most reprehensible practice on the part of the Central News Agency. In *The Times* and other London dailies of February 8th, telegrams appeared purporting to be dated from the seat of war between China and Japan (Wei-hai-wei, *via* Talienwan, February 5th). The telegram, as it finally appeared in *The Times*, contained rather more than 500 words out of the 655 words originally sent out by the News Agency in question. According to one of the leading Japanese journals, the *Kobe Chronicle*, the original message, "the origin of which was Tokio or

Digitized by Google

Yokohama," contained only 216 words, so that two-thirds of the message as sent to the London Press was manufactured in London. This is a serious charge, and it is to be hoped that the Central News Agency will be able to satisfactorily meet it, as it is most important that the public should not gain the impression that lengthy items of foreign intelligence appearing in the Press are manufactured in Fleet-street, where not only the offices of the London but also those of the provincial dailies are centred. It is recognised that the great London dailies observe the utmost care in the preparation for publication of their telegraphic news, and especially is this the case with *The Times*, which has a grand reputation for special telegraphic information.

Factories and Workshops Bill.—The House of Commons Grand Committee on Trade met for the first time last week, and discussed Clause 1 of this Bill. On the question of the provision enabling the Home Secretary to increase the cubic space "for any period during which artificial light is employed," Mr. W. Allan moved to add after "artificial light" "other than the electric light." This was supported by Mr. Mundella and accepted, placing the electric light in a distinctly favourable position so far as regards the carrying out of the provisions of this Act. In factories and workshops where space is limited this amendment of Clause 1 will enable the full staff of hands to be employed for overtime hours as for ordinary hours, whereas where gas and other illuminants are employed the extra cubic space required necessitates a considerable reduction in the number of employés who can be kept for overtime work.

Falmouth.—Notwithstanding that the question of lighting this town by electricity is under the consideration of the Local Authorities, a committee was appointed by the Town Council at its meeting on Monday last to consider the question of purchasing the local gas works.

Fareham.—Some alarm is being felt by many prominent residents of this town as to the possible cost of the litigation between the District Council and the Fareham Electric Light Company. A deputation was appointed at a meeting of ratepayers held last week to approach the Directors to see what steps could be taken to stop the litigation.

Hospital Lighting.—The Brook Hospital Committee, at the meeting of the Board last week, reported having given careful consideration to the question of the appointment of an electrical engineer for the installation of the electric light at the Hospital, and recommended that the Committee be authorised to employ Prof. A. B. W. Kennedy to design the installation for the electric lighting, to draw the necessary reports, plans, and specifications, and supervise the execution of the works, at a commission of 5 per cent. on the cost thereof, out-of-pocket expenses and the wages of the clerk of the works being extra. After some discussion the report was approved.

Hove (Sussex).—At the meeting of the Urban District Council last week, on the report of the Works and Improvements Committee, attention was called to the cost of lighting the public streets by electricity. Mr. C. T. Cheesman, Chairman of the Committee, stated that the Surveyor was preparing a report relative to the comparative cost of gas and electric light, but, so far as the Committee were at present advised, he stated that the price of electric current was so much higher than that they were now paying for gas that he did not think the Council were likely to substitute electricity.

Huddersfield.—At its meeting this week the Borough Council instructed the Town Clerk to take the necessary steps to obtain borrowing powers for a further £50,000 for electric lighting purposes.

Institute Lighting.—The premises of the Central Art Department of the London Technical Education Board, situate in Bolt-court, Fleet-street, E.C., have been wired throughout for the electric light by Messrs. Wenham and Waters, current being taken from the City of London Company's mains. Two 200-c.p., seven 150-c.p. and two 100-c.p. Sunbeam incandescents are used. Provision has also been made for two 2,000 c.p. arcs being provided for photographic work. A large number of smaller candle-power incandescents are used in the class-rooms.

Islington (London, N.).—In a report issued on Wednesday the Finance Committee of the Vestry submit a correspondence which has passed between the Vestry Clerk and the Comptroller of the London County Council with reference to a loan of £51,000, which the Vestry require for electric lighting purposes. The Finance Committee of the Council, having obtained the consent of the Treasury, are prepared, as an alternative to their proposal, to sanction the loan for land, buildings, and bare copper mains (estimated to cost £18,000) for 50 years, and for all other machinery (estimated to cost £33,000) for 20 years, to recommend the Council to sanction a mean period of 42 years for the repayment of the whole amount "on condition that if any portion of the machinery requires to be renewed during this mean period it shall not be made the subject of a new loan." The Vestry's committee point out that acceptance of this condition would render it necessary, besides providing for the annual repayment of capital and interest, to further burden the undertaking (or possibly the ratepayers) during its earlier years by the creation of a renewal fund to provide not only for the wearing-out of machinery, but for the possibility, owing to the advance constantly taking place in electrical science, of portions of such machinery becoming obsolete during the currency of the loan. Further, it is considered doubtful whether the Council, in sanctioning a loan, has power to limit the period for repayment provided by Section 8 of the Electric Lighting Act of 1882 and Section 190 of the Metropolis Management Act, 1855. The Vestry's Committee, therefore, advise that counsel's opinion be taken on this point, and meanwhile the Vestry Clerk is asked to make a formal demand for the County Council's sanction to the loan.

Leyton (Essex).—The Hall Building Committee of the District Council have presented an interesting report on the subject of lighting the Town Hall and Municipal Buildings by electricity. The estimated cost of this lighting is £1,250, with a further expenditure of about £400 if the whole of the buildings are lighted. The Committee are of opinion that the buildings, including the present offices, should be lighted by electricity rather than gas, although the former is more costly than the latter, and the Committee recommend that they should be authorised to arrange for specifications, &c., and that tenders be invited for the necessary work. After a brief discussion the Committee's report has been adopted.

Litigation.—We learn that the Edison and Swan Company have commenced legal proceedings against an electrical firm and one of the licensees under the Company's holders patents, for breach of the licence in giving to customers a larger discount than the allowed maximum. For some time past there have been rumours that some of the licensees were selling holders at a lower price than that fixed by the Company under the terms of the licence, and recently a committee of the licensees was, we understand, formed in order to establish "an honourable understanding" among the licensees that this underselling should be discontinued. The terms of the licence are very stringent, as will be seen from the following:—

"The licensee shall not make or allow any discount commission rebate return gift or allowance to customers greater than the discount from time to time allowed by the Company."

The Edison and Swan Company gave notice on December 31st last that, should any future breach of this condition be proved, they would take legal proceedings for an injunction and for damages, and it is hoped that the legal proceedings now being instituted will put an end to any unfair advantage being taken.

London County Council and Sardinia-street Station Extensions.—At the weekly meeting of the London County Council, on Tuesday, it was agreed, on the recommendation of the Building Act Committee, "That, subject to the provisions of Section 76 of the London Building Act, 1894, the consent of the Council be given to the erection and construction of a dynamo room (over and in connection with the boiler house) at the Metropolitan Electric Supply Company's premises in Sardinia-place, Lincoln's Inn-fields, to exceed in extent 250,000 but not 450,000 cubic ft., and to be used only for the purposes of generating electricity, as shown by the plans and particulars submitted on behalf of the Company, on condition that the whole of the work be executed to the satisfaction of the district surveyor; and that if the said plans, particulars or application be hereafter found to be inaccurate in any respect the said consent shall be null and void."

Mansion Lighting.—The Duke of Montrose has entrusted to Messrs. Drake and Gorham, of 66, Victoria-street, Westminster, S.W., the lighting of his town house, 27, Pont-street, S.W. The entire building is to be lighted electrically.

Melrose.—It is reported that a firm of electrical engineers have offered to undertake the lighting of Melrose. The price suggested to be charged for current is 7d. per unit, upon a guarantee of 1,000 lamps of 16 c.p.

Mildenhall.—An extensive range of buildings is being erected at Mildenhall as a workhouse and infirmary for the Mildenhall Union. The contractors are Messrs. Kerridge and Shaw, Cambridge. The question of lighting has not yet been settled, but in all probability the electric light will be adopted, on the score of economy for no other reason, as gas is very expensive in the district.

Mill Lighting.—A complete installation of 1,200 lights is being fitted in the Valley Mills of Messrs. James Nelson and Co., of Nelson, Lancs., the work being carried out by Messrs. Coates Bros. The dynamos are being built by the Coventry Electrical Engineering Company, and will consist of two 600-light machines running at 500 revolutions, rope-driven from main shafting, and one 250-light pilot dynamo driven by separate engine. The mill

Digitized by Google

will be lighted entirely by electricity, gas being excluded.——It is stated that the extensive mills owned by the Harrington Mill Company at Long Eaton, Derbyshire, are shortly to be lighted by electricity, and that it is intended to form a company for the purpose, in order that current may be supplied to several factories in the neighbourhood.

NEWCASTLE.—Prof. A. B. W. Kennedy's report upon the proposal of the Corporation to purchase the undertakings of the two local electric lighting companies has been issued. Prof. Kennedy points out that the charge for current by both companies is exceptionally low, and it is therefore necessary to consider how far it is financially advisable for the city to take over the businesses. There is nothing in the Acts of Parliament nor in the usage of the Board of Trade which will compel the companies to sell; this therefore involves the condition that the companies are willing to sell at a price at which the Corporation is ready to purchase. As the Newcastle Corporation is able to borrow money at a low rate of interest, a total of 5½ per cent. per annum would pay both interest and sinking fund charges. To find the amount of earnings of each of the companies which would be available for payment of interest and sinking fund, Prof. Kennedy has subtracted from the gross profits earned in each year an amount of 1 per cent. on the capital as representing such depreciation allowance as the Corporation would probably have to make if the works were purchased. Taking the two companies together, the total capital actually expended has been £103,911, while the net profit (after allowing 1 per cent. depreciation) has been sufficient to pay 5½ per cent. on £100,200 capital. It would not be advisable for the Corporation to attempt to buy one company and not the other, and it is doubtful whether such a course would be sanctioned by the Board of Trade. Although the companies have not yet formulated their views on the matter of the values of their undertakings, it is reasonable to suppose that they would not sell at anything like the figures above quoted, and therefore it remains to be considered whether such economies could be effected in the cost of working as to warrant the Corporation's purchasing; and further, whether the town would materially gain by the electric lighting works becoming the property of the municipality. One way by which the Corporation could economise would be by connecting the two stations, so that one only need run continuously, the second supplying current during the time of heavy load. This is electrically possible, although there are some practical difficulties, and considerable expense would be involved. As at present officered, the cost of management of the companies is very low, and it is questionable whether any economies could be effected in this direction outside the directors' fees, which amount to no more than £341 per annum for the two companies. As this small sum is paid to gentlemen who render very able and effective services to the companies, it is probable that the Corporation would have to pay a much larger sum for equivalent services. Although the works of the two companies are in such a state that they may be run by the companies themselves with very little additional expense, it is doubtful whether the Corporation would be content to carry out the work under existing conditions. Taking the actual figures for the working during 1894 it might be possible for the Corporation to have done the same work as the companies for a sum of £1,200 less, but it is doubtful for many reasons, whether the Corporation would have actually effected the whole of this saving. Prof. Kennedy regrets to say that he is driven to the conclusion that it could not pay the Corporation to purchase the undertakings and goodwill of the two companies at any price covering the premium approximate to that which has been suggested by one of the companies. Finally Prof. Kennedy considers that the whole question resolves itself into the price charged per unit, and as this is exceptionally low at Newcastle, the financial success of the Corporation's proposed purchase is dependent upon their ability to increase the price to 6d. per unit, as they would be entitled to do by Act of Parliament. Prof. Kennedy could not suggest to the Corporation that they should raise the price, as he presumes this is practically out of the question, but it is undoubtedly the key to the whole situation. The price per unit charged by the Newcastle companies is 4½d. for light, and 3d. for power or day supply.

NORTHAMPTON.—At the last meeting of the Town Council a proposal by the Highways and Lighting Committee to light the market square by means of four 1,000-c.p. arcs at an annual cost of £70 was referred back for reconsideration.

OSSETT (YORKS.).—The Town Council have under consideration the question of the lighting of the town by electricity.

OXFORD.—Owing to a steady increase in the Oxford Electric Company's business, it has been found necessary to add a 100-kilowatt plant in order to accommodate the coming winter's demand. The Company have placed orders with the Electric Construction Company for a dynamo and exciter, and with Messrs. J. and H. McLaren, Leeds, for an engine. A considerable extension of the Company's mains has recently been made and further extensions are now in progress.

PERTH.—As mentioned in a recent issue, it was decided some few weeks back to light the water works electrically. It being pointed out by the Water Works Commissioners that the work would be much facilitated by this change. Tenders were issued, and the contract was placed with Messrs. Lowdon Bros., Electrical Engineers, North Tay-street, Dundee. The firm have used an 8-H.P. engine which was originally put down for pumping feed-water to the boilers; and the installation includes a 30-ampere "E.C.C." dynamo. The light was switched on on Monday last by Lord Provost Dewar, who said it was the first installation of the electric light in a public department in Perth, and he believed there would soon be a further extension. From the present installation there would be power enough to light the municipal buildings as soon as they were completed. There was considerable water-power running to waste at the city mill, and this could be profitably utilised for driving electrical machinery. Mr. Davidson, the manager of the water works, was complimented upon the success of the installation, which has been carried out by Messrs. Lowdon Bros. to his plans.

REDDITCH.—The *Indicator* in a recent issue calls attention to the advantages which would accrue to this town if the electric light were adapted. It would appear that Redditch as a town is immensely attractive from many points of view, but one of these is certainly not its lighting arrangements. It is true that the Gas Works are returning good dividends, but all the same the public lighting leaves much to be desired. Complaints have been made of the quality of the gas, and it is probable that an agitation for the adoption of the electric light will shortly be started.

RHYL.—At the last meeting of the Urban District Council an application was received from a Birmingham firm asking for permission to construct an electric railway between Rhyl and Prestatyn, and the clerk was instructed to obtain further particulars.

ROTHESAY.—At the last meeting of the Harbour Trust and Town Council it was resolved, on the recommendation of the Harbour Committee, to postpone the proposal for the electric lighting of the harbour for this year, as it had been found that the light would not be available before the end of August.

ST. PANCRAS (LONDON, N.W.).—The Electricity Committee, at the meeting of the Vestry on Wednesday, reported that with regard to the Board of Trade's recommendations in relation to the recent explosions in Euston-road and Gee-street the Vestry were now carrying out the following works:—(1) Ventilating the culverts and manholes with the view of getting rid of any accumulation of escaped gas through leakage from defective gaspipes; (2) reducing the cubic capacity of the manholes, as far as practicable, by filling them with bricks; (3) removing the present bearers and insulators in the manholes and substituting a new form of bearer and insulator with a larger insulating surface; and also, as far as it is practicable, taking steps to detect any incrustation on the insulators in the culverts. Mr. A. Sweet, in moving the adoption of the Committee's report, said that it did not follow that because the Board of Trade recommended the Vestry to do certain things the latter were bound to do them. In one instance a precaution, adopted at the instance of the Board of Trade, had proved an utter failure, and had to be abandoned. The motion was adopted. Mr. Clements objected to the Vestry borrowing from the County Council at the rate of 3¼ per cent. when, upon their own bonds, they could get money in the City at 3 per cent., or even less. He gave notice of his intention to move that the Vestry thus raise the £65,000 still needed for electric purposes. Dr. Bell remarked that the loan would be taken up locally at less than 3¼ per cent.

SHOREDITCH (LONDON, E.C.).—The Vestry have received a report from the Electric Lighting Committee that the draft specification for the construction of destructors, furnaces, boilers, flues and accessories, for which tenders are to be received by May 20th, has been settled. The Committee have decided to defer advertising for the electrical contracts until this section of the work has been definitely settled. A further consideration of the matter will take place at the next meeting of the Vestry, when tenders will be before the members. The designs for baths and wash-houses, for which an outlay of £30,000 is to be incurred, are to include provision for heating and lighting by electricity.

SOUTHAMPTON.—The Works Committee of the Corporation in their report recommended that professional advice be obtained to assist them in valuing the works of the local electric light company in reference to the proposed purchase by the Corporation. It was pointed out by several members that the company having been established so short a time no difficulty should be experienced in ascertaining the value of its electricity works. The Committee's proposal was, however, finally adopted.

SOUTH SHIELDS.—Mr. G. W. Willcocks, C.E., last week held a Local Government Board inquiry, at the Town Hall, into an application of the Corporation to borrow the sum of £28,300 for electric lighting purposes. The Town Clerk having explained the nature and scope of the scheme, the electrical engineer (Mr. J. A. Jeckell) explained the system proposed to be adopted, and the streets

through which the mains would be laid. They were in a ring, and so arranged that any section could be cut out for inspection and testing. The plant intended to be put down at first would be capable of supplying current for 2,500 lamps. The capital cost of the works, based as far as possible on the accepted tenders, was estimated as follows :—Boilers and pipes, £1,809 ; pumping plant, £905. 14s. 3d. ; engine room plant, £8,003 ; spare gear, £205 ; cables, £3,340 ; pipes, &c., £1,506. 2s. 9d. ; arc lamps, £793. 11s. ; meters, £475 ; new flagging stones, £325 ; extra transformers, £450 ; jointing on consumers, £200 ; land purchase-money, £4,400, and interest and legal expenses, £250 ; buildings, £3,500 ; deputation and office expenses, £100 ; contingencies, £500 ; engineering supervision, £600 ; printing specifications, £100 ; travelling expenses and testing plant, £100 ; Provisional Orders, £360 ; experts' report, £26. 5s. In addition to these items a further expenditure of £300 will be necessary for low-potential cables to be constructed in Ocean-road. Alderman Reynoldson (Chairman of the Electric Lighting Committee) said the entire machinery would be of a permanent kind, and of the very best and most modern type.

SURBITON (SURREY).—The Urban District Council propose at an early date to consider the question of lighting the district electrically.

TECHNICAL EDUCATION.—The annual report of the Technical Education Board of the London County Council was submitted at its last meeting. The report states that "working, as it does, in harmonious co-operation with existing institutions, the Board is glad to recognise, at the close of its second year's existence, a marked increase alike in the number of classes for every branch of technical and manual instruction, and in the attendance at such classes."

TELEGRAPH WIRE EXPORT TRADE.—April was anything but a satisfactory month as regards the export trade of this country in telegraph wire and apparatus connected therewith. The value of the exports only reached a total of £35,544, as compared with £186,739 in April of last year. The returns for the first four months of the year indicate the depression which at present hangs over this branch of trade, the total value of the exports being £99,746, against £452,018 in the corresponding period of 1894.

THEFT.—Harold Delane Radcliffe, aged 20, described as an electrician, lately in the employ of the Great Northern Railway Company, was charged at North London with stealing a number of tools and electric switches. The tools were the property of a fellow-workman, and the switches belonged to the Company. The prisoner had been in custody a week, and, as there seemed to be no object in the theft, and no reason whatever for the foolish act, he was discharged, bail being accepted for £20 to come up for judgment if called upon.

TRAIN LIGHTING.—Most of the carriages on the London, Tilbury, and Southend Railway are now lighted electrically, in substitution for the lightless and dirty oil formerly used.

YARMOUTH.—At this week's meeting of the Great Yarmouth Town Council, the surveyor reported that the monthly loss on the electric lighting undertaking was gradually diminishing. 3,900 lamps have been connected up or applied for by 75 customers. Mr. W. H. Preece presented a lengthy report on the proposed extension. Mr. Preece recommends that the lights in the streets should be doubled, but to this proposal the Council's surveyor takes exception. Mr. Preece anticipates that in two or three years the Corporation will be supplying 14,000 lamps, and that the existing plant is inadequate, and that extensions are necessary. He recommends the Council to at once provide plant equal to supplying current for 9,000 additional lamps, and his detailed estimate for this work amounts to £15,500 ; and the Electric Committee recommend the Council to apply for powers to borrow £15,500 accordingly. The Committee's report was unanimously adopted. It was also decided to place 20 25-c.p. incandescents on the band-stand in the Beach Gardens.

COMPANIES' MEETINGS AND REPORTS.

Brazilian Submarine Telegraph Company (Limited).

The forty-third ordinary general meeting of the shareholders of the Brazilian Submarine Telegraph Company (Limited) was held at Winchester House, Old Broad-street, on Wednesday, under the presidency of Sir John Pender, G.C.M.G., M.P.

The SECRETARY (Mr. Richard Collett) having read the notice convening the meeting and the minutes of the last meeting, which were approved by the present meeting,

The CHAIRMAN said : Gentlemen, I presume that you will take the report and accounts as read, but before moving the resolution I will, as usual, go over in some detail the proceedings of the last six months. The receipts for the half-year ended December 31, 1894, were £104,926, while for the previous half-year they were £94,679, showing an increase of £10,247. The receipts from messages show an increase of £10,192, and those from miscellaneous receipts from interest, rents, and transfer fees an increase of £55, resulting in a net increase, as before stated, of £10,247. The number of messages for the half-year ended December, 1894, was 96,917 ; and for the half-year ended June, 1894, 85,414, being an increase of 11,503 in the December half. The average exchange value of the Brazilian currency was, in the December half-year, $10\frac{3}{16}$d., and in the June half-year $9\frac{1}{2}$d., being an increase of $1\frac{1}{16}$d. Leaving the credit side of the revenue account, and taking the expenditure, we find that the total charges falling upon the half-year amount to £36,772, compared with those of the previous half-year, £20,269, showing an increase of £16,503. This large increase is due to the fact that heavy expenditure for repairs of cable and renewal of both shore ends at Pernambuco, the landing-place in Brazil, falls upon the half-year under review, while there were no expenses of a similar character in the previous six months. The total cost of the operations referred to, including charter of repairing steamer and new cable used, was £21,273 ; but allowing for the cable recovered, which can be used elsewhere, the total cost is reduced to a net sum of £16,402, which practically accounts for the increase of £16,503 I have given as the increase in working expenses for the half-year. My reference to the cost of this repair and renewal will serve to remind you of the heavy expenses that must from time to time occur in repairing the cables and in maintaining the efficiency and regularity of the service which has become indispensable to the Governments and commercial communities of the world. I may take this opportunity of stating that, in consequence of our having provided a second cable for the public use, there has not been an interruption of service on our route since March, 1884, a period of 11 years. The item of debenture interest and sinking funds shows a more satisfactory result, for there the expenditure is £4,841 against £12,880 in the half-year ended June last, being a reduction of £8,039, due to the termination of the interest and sinking fund in respect of the first issue of debentures on July 31st last, when the balance of that issue was paid off. Deducting the saving last referred to, £8,039, from the increase in expenses of working and repairs and renewals, £16,503, there is a net increase in charges of £8,464. But taking both receipts and expenses into account, there is, after providing for income tax, a net profit for the December half-year of £61,822, which, compared with that for the half-year to June, 1894, £59,793, shows an increase of £2,029, which, under the circumstances cannot, in my opinion, be looked upon as other than satisfactory. I have before me the heads of each increase and decrease, but I do not propose going through them in detail unless desired to do so. I may say, briefly, that the expenses in London show a small increase of £31. Those at the stations are greater by £931, which is chiefly caused by additional expenses connected with agencies established abroad for the protection of the interests of your Company. The expenses under the other heads show in the aggregate a decrease of £861. As usual in the first half of the financial year, two quarterly interim dividends at the rate of 6 per cent. per annum have been paid, leaving £24,324 to be dealt with. Of this your Directors have transferred £20,000 to the reserve fund, and the balance, £4,324, is carried forward to the current half-year. The reserve fund now amounts to £722,000, a satisfactory result after some 21 years' working. A strong reserve is absolutely necessary for such a Company as ours. We have to maintain and repair cables of great length lying in very deep water. One cable has been submerged 21 years, a period at one time thought to be beyond the "life" of a cable. With age and wear-and-tear we must expect more frequent breaks, and be prepared for much heavier expenditure in repairs and renewals of cables. With reference to the probability of the purchase of the cables of our ally, the Western and Brazilian Telegraph Company, by the Brazilian Government, I can afford no information. The Government has been authorised to acquire the cables at a certain price ; but upon investigating the matter, and fully considering all the surrounding circumstances, they may decide not to use the power given or postpone the exercise of it to some future and more convenient period. In the meantime, your Board are endeavouring to make satisfactory arrangements with the Government, whether they acquire the coast cables or not, for the working of the traffic in a way beneficial to both the Government and the people of Brazil, and to telegraph companies also. As traffic grows, reductions in rates are made. Your Directors are of opinion that an efficient and high-class service can be best maintained in combination with lower rates, as and when justified, by mutually beneficial arrangements being agreed upon between the Government, your Company, and the other cable enterprises in Brazilian waters. The lines of the Pacific and European Telegraph Company (Limited), in which we are largely interested, have now been opened for a year, and have worked with satisfactory results. The traffic grows from month to month, and it forms a very valuable feeder to the allied cable companies dealing with the traffic to and from the West Coast of South America. £55,660 appears in the balance-sheet as paid for 5,566 shares of £10 each in the Azores Company, in which we are interested, and which may eventually connect the present system with the North American Continent. I have now given you some particulars in detail, and when you look at the successful working of the half-year, and at the large reserve fund which we have now at our credit, I think you will agree with me that we occupy a very strong position at the present time. We, however, also require to maintain a thoroughly efficient system, and we can better maintain that system if all the parties interested in it join with us heartily in carrying out the views which we hold to be essential for the well-being of any submarine telegraph company. I have told you something of our prosperity. I have now to announce the death of our Managing Director, Mr. Fuller, who was associated with the Company from its inception. You cannot in any way point to the great prosperity of this Company without associating the late Managing Director's name with it. He had retired from the service, and we had agreed to pension him, as I

think it was our duty to do. He only lived a few days after he knew that he had been awarded this pension, and I can only express, on behalf of my colleagues and myself, our deep regret at losing an old colleague so closely associated with us, not only in the commercial work of the Company, but also on our Boards, where we met every alternate week. I believe you will join with me in an expression of sympathy to those he has left behind him the widow and family—and authorise me to convey to them the condolence which I will communicate to them on the part of the Board, and which I shall also be glad to express on behalf of the body of the shareholders. I have referred to the non-completion of the purchase of the Western and Brazilian Company by the Brazilian Government. Until that question is dealt with we shall probably be at a standstill. I should be glad to see that matter settled, but we cannot hasten it. It is in the hands of the Brazilian Government, and I have no doubt that the energy which the Western and Brazilian Company has shown in obtaining the approval of the purchase by the Government will also be exhibited in the direction of pushing the Government on to an early settlement of it. When that question is disposed of we may have to deal, not with a Brazilian Company, but with the Brazilian Government, and I may remind you that for 21 years of our existence we have worked in the most friendly relations with that Government. I remember well in the early days of this Company going with Captain Sherard Osborn, who was the brother-in-law of our Managing Director, to wait upon the Emperor of Brazil at Claridge's Hotel. Those are by-gone days, but the remark which his Majesty made to me at the time was one that I shall always remember with interest. He said, "We cannot give you money, but I think we have got such a trade as will give you a good return on any money you may invest, and you shall have every encouragement that we can possibly give you." I believe that those words were honestly and earnestly expressed, and I have the belief still, and I hope before long I shall be able to tell you that the relations between this Company and the Brazilian Government are as good and sound as the relations of the submarine companies generally are with the Governments of other nations. Submarine telegraphy is a broad question. No nation can do without it, and the position we hold now among the nations of the world is a very proud one. I therefore appeal to any Government that if they want to maintain a thoroughly efficient system of submarine telegraphy they must act in touch with the companies who conduct it, and who are dependent to a great extent on a fair and open field, with no favour excepting the favour of being protected against any innovations which might be destructive to the interests of the Company. We have approached the Brazilian Government in a spirit which I hope will bear fruit. I have always said, and I repeat that in connection with these telegraphs there may be different companies, but the different companies ought to act always as one, and until that system is observed the shareholders will suffer. I believe that where boards get to pulling against one another it is always the shareholders who suffer. Therefore I ask you to give your Board a full and hearty support in endeavouring to maintain such a system as will give fair dividends and satisfy the telegraphing community of the world. With these remarks I beg to move

"That the report of the Directors and the accounts to December 31, 1894, now submitted, be approved and adopted."

The Hon. W. St. JOHN BRODRICK, M.P.: I have much pleasure in seconding the motion.

Mr. W. GRIFFITH remarked that the Chairman's speech was so full of information that it was difficult to find an opportunity of asking a question, everything being anticipated beforehand. Their Company had been most successful, and he thought that the Directors had done right in investing in allied companies, but he considered that when a new company was brought out whose business was likely to assist them, the shares and debentures of such new company ought to be offered to the shareholders of the old company. The latter would then be able to support the Directors by taking up the shares, while the shareholders would be able to benefit themselves in getting a good return.

The CHAIRMAN: The policy you recommend to the Board is the policy which the Board have always practised. I think you are referring to the shares which I have alluded to—the £50,000. They are now in the hands of the Brazilian and Eastern Companies, and so that we have never gone to the public with those shares, which form part, practically, of the capital of the companies in which you are shareholders. You may depend upon it, that if we are bringing out any new company or any important enterprise, our own shareholders will have the first offer of the capital. I am reminded that in the case of the Pacific and European Telegraph Company the debentures were offered to the public, but they were first offered to shareholders. He then put the motion and declared it carried unanimously.

On the motion of Mr. JOHN NEWTON, seconded by Mr. GRIFFITH, a resolution was passed expressing the deep regret of the shareholders at the death of Mr. Fuller, and requesting the Chairman to convey to the widow and family of the deceased gentleman their sympathy and condolence.

Mr. ROBERT TAYLOR afterwards proposed a vote of thanks to the Chairman and Directors for their admirable management of the Company's affairs.

Mr. NEWTON seconded the motion, which was carried unanimously.

The CHAIRMAN stated that he had received a letter from a shareholder complaining that he was not invited to the banquet on the occasion of the 25th anniversary and "silver wedding" of the submarine telegraph companies. Taking in all the companies concerned, there would have been about 20,000 persons to invite if all had been invited, and this was simply impossible. There was something higher in connection with the celebration in question than simply £. s. d. It was a celebration of what one of the greatest living statesmen described to him as "the greatest achievement in the world's history." He believed that the shareholder who had addressed them had done so through misunderstanding the position. On behalf of his colleagues and himself he warmly thanked the shareholders for the renewed confidence they had shown in them by again according them a vote of thanks.

China and Japan Telephone Company (Limited).

The twelfth ordinary general meeting of the shareholders of this Company was held at the office, 14, Austin Friars, London, E.C., on Tuesday, under the presidency of Mr. H. Grewing.

The SECRETARY (Mr. Alexander B. Chalmers) having read the notice calling the meeting,

The CHAIRMAN remarked that there was very little for him to state, as all the information which the shareholders might find desirable in connection with the past year's operations would be found in the report. The amount of the subscriptions had been better than it was in the previous year, and so far the Company was making steady though slow progress; but, owing to various circumstances, partly through the war between China and Japan, and partly on account of epidemics which had existed, especially in Hong Kong, the sales fell off to some extent, as did also the profits, which were also markedly affected by the fall in exchange. However, in consequence of the recent rise in silver, and the conclusion of the war, it was to be hoped that these matters would rectify themselves, and that in the present year they would not only improve the total of their sales and make a corresponding profit, but also add considerably to their subscriptions. China had, so far, not taken any more kindly to telephones than it did in former years, but now that the war had changed the condition of things, the Chinese might alter their views on the subject, and might come under the Company's exchanges. He concluded by moving the adoption of the report and accounts.

Mr. THOMAS LLOYD seconded the motion, which was carried unanimously.

Resolutions were afterwards passed re-electing Mr. Lloyd to his seat at the Board, reappointing the auditors (Messrs. Price, Waterhouse and Co.), voting the Directors 200 guineas as remuneration for their services in the past year, and according a vote of thanks to the Chairman and Directors.

The Directors' report states that revenue account, after charging debenture interest, shows a sum of £387. 6s. 8d. to credit, which has been transferred to profit and loss account. Including £710. 18s. 10d. brought forward from 1893, this account shows an amount of £1.098. 5s. 6d. to credit. From this sum it is proposed to write off £526. 17s. 1d. in reduction of goodwill and expenditure on exchanges, carrying forward the balance, £571. 8s. 5d. The profit for the year shows a falling off as compared with that of the preceding year, and although the actual amount received for subscriptions has exceeded that of the previous year, the loss on remittances has been heavier. The business at the Hong Kong branch was much interfered with owing to the outbreak of the plague, which extended from April to July, and was then followed by two typhoons in close succession, necessitating considerable reconstruction of lines owing to the damage done.

The Bournemouth and District Electric Supply Company (Limited).

The annual ordinary general meeting of shareholders in this Company took place at the offices of the Company, Bournemouth, on Friday last, Mr. A. H. Sanderson presiding.

The CHAIRMAN moved the adoption of the Directors' report, which stated that the number of lamps connected to the Company's mains on December 31st was equivalent to about 19,000 8 c.p., an increase of 4,500 for the year. The accounts show a profit of £1,642. 1s. 9d., and after paying interest on debentures, interest, and commission on loans for capital purposes, &c., a balance of net profit remains of £395. 6s. During the year considerable additions and extensions were made at the generating station and in connection with the mains and system of distribution, all of which were rendered necessary by the steadily increasing demand for current, and the funds required for these purposes were obtained from the Brush Provincial Company, on loan, pending a rearrangement of the Company's capital account, and a further issue of shares or debentures. The demand for electric current in Bournemouth was steadily increasing, and the regularity of the supply from the Company's mains gave general satisfaction.

The CHAIRMAN continued: The applicants for supply of electric current consisted of a large number of shop proprietors, and of small rather than large consumers, which in his opinion testified to the general popularity of the light, and augured well for the future of the Company's business. The Company's business had expanded by about 29 to 30 per cent. during the year, which was certainly a gratifying result. The maximum current ever demanded from the Company's machinery at any one time was made on Christmas Eve last, and amounted to 164 amperes, as compared with 132 amperes on Christmas Eve 1893, or an increase of 26½ per cent. upon the maximum previously demanded. A large sum had been spent upon extensions to buildings and plant, as well as upon improvements and modernisation of the Company's system of mains, the single-cable high-tension mains having been replaced by concentric cables throughout the system; a large number of transformer pits had been constructed, and a network of new low-tension cables had been laid. These outlays were incurred with a view both to increased economy in distribution and increased regularity and reliability of supply, and they had already borne good fruit in these directions though the full benefits to be derived would doubtless be still more apparent in future years. The Company had also duplicated the trunk

Digitized by Google

main from the works to the centre of the town. It had also been necessary to put down new plant at the lighting station, and to lay mains in new districts, in order to cope with the largely increased and increasing demand for current throughout the Company's area of supply. The engine room had been considerably enlarged during the year, and further extensions to buildings and plant were contemplated in the immediate future. The necessary funds for the carrying out of these works had been, as stated in the report, borrowed from the Brush Provincial Company, pending a re-arrangement of the Company's capital at an early date, and this loan appeared in the general balance sheet under the head of bills payable. He was pleased to be able to inform the shareholders that the first three months' working of 1895 showed satisfactory results, and he considered that the Board were justified in adopting the course on which they had lately decided, in reducing the charge for current from 8d. to 7d. and 5d. per Board of Trade unit to the consumers, between whom and the Company, he was glad to say, very cordial relations existed. Experience both at Bournemouth and elsewhere had demonstrated the impossibility of a very small lighting station, with its comparatively high maintenance costs, being made to pay, as an instance of which the Bournemouth station, with its present output, and with its lamp connection of upwards of 19,000, was only now, after seven years' hard struggle, entering upon a profitable stage. The Electric Lighting Company (Limited) had become very large shareholders in the Bournemouth undertaking, and the Bournemouth Company had been fortunate enough to secure the services of Mr. B. Percy Sellon as a Director. The shareholders were to be congratulated upon having secured the services, as managing engineer, of Mr. Henry M. Sayers, who had had a long experience in electric lighting matters, dating back from the very commencement of electricity supply in this country. Mr. Sayers had already rendered good services to the Company, and had been ably seconded in his efforts by Mr. Ingram (the station superintendent) and the staff at the works, as well as by Mr. Charles Offer, their secretary.

The report was adopted, the retiring Director (Mr. Sanderson) re-elected, and after a vote of thanks to the Chairman the proceedings terminated.

Dover Electricity Supply Company (Limited).

The first annual meeting of this Company was held at Dover on Friday week, under the presidency of Sir William Crundall, the Chairman of the Company.

The report of the Directors stated that the contracts for the generating station buildings, offices, and street work had been completed, and part of the generating plant had been delivered and erected, so that the Company had been enabled to commence the supply of current under the contract already entered into with the Corporation for the public lighting of the streets. A contract with the War Office for the lighting of the gun turret on the Admiralty Pier and several contracts with private consumers had also been entered into, and current for private lighting is being supplied. The Directors confidently look forward to having the equivalent of at least 5,000 8-c.p. lamps connected to the mains by the end of the year. Inquiries have been received for the supply of power for working cranes and hoists, from which considerable revenue is anticipated.

The CHAIRMAN, in moving the adoption of the report and accounts, said that although the works were in a fair way towards completion and were indeed practically complete, they had not yet commenced to supply private consumers; therefore their revenue account had not fairly commenced. Out of the Ordinary share capital of the Company £25,000 had been taken up, of which only £4,000 was applied for locally, so that the balance has been provided by outside friends. With regard to plant, they had eight engines in all, which combined 640 H.P.; two boilers, each of 200 H.P., were already installed, and two more ordered. At the end of the year 1894 they had expended £27,000, and estimated the expenditure up to the present at about £46,000. They had laid down pipes in the streets to the length of 14 miles, and had cabled six miles with an extra mile of cable in the most important thoroughfares. In the course of a few days they would be able to connect up the private consumers who had already wired their houses. The charge for current was at present 8d. per unit, but as they got more customers they would be able to reduce the charge. They were already supplying arc lights equal to about 2,200 8-c.p. lights, and hoped soon to have lights equal to 3,000 or 4,000 more, equal in all to 5,000 or 6,000 8-c.p. lights. As regards their future prospects, they were negotiating with several consumers, and intended to make the Company a great success. They had put down plant capable of supplying the whole town, and, if necessary, could, with extra machinery, supply adjacent towns. They would not expect him to declare a dividend at that meeting, but he hoped that the time was not far off when they would declare a substantial one, and that the shareholders who had shown an interest in the undertaking would not have shown it in vain.

Mr. VAN TROMP said everything necessary for carrying on a large business had been provided for. He would suggest to the owners of house property in Dover that they should adopt a course which he suggested in the City of Bath. It was extremely difficult to induce occupiers to wire houses which they might only occupy for a comparatively short period, but if landlords could see their way to do the wiring, and charge a moderate sum extra in the rents, the occupiers would be very glad to have the light. That plan had been adopted at Bath with beneficial results.

Mr. W. G. LEWIS said that at Buckland, an adjacent district, they had the light in their church, and were very well pleased with it. They had 64 lamps, and on the first Sunday night that they used it the meter showed the cost during the evening service to be 3s. 8d.; the next week it was 3s., and on the last Sunday it was 2s. 8d.

The CHAIRMAN said he was afraid they would not get much dividend out of that, but he was glad to hear that the churchwardens of Buckland were perfectly satisfied. With regard to the wiring of houses, he had agreed with some of his tenants that, if they liked to do the wiring, he should be prepared, within certain limits, to take the fittings over on their removal. He felt sure that houses wired for electricity would be more quickly let than where there was only gas.

Sir William H. Crundall and Mr. B. H. Van Tromp were re-elected as Directors, and Mr. R. H. Marsh as auditor.

Western and Brazilian Telegraph Company (Limited).

The following report of the Directors of this Company for the half-year to December 31st last will be presented at the twenty-ninth ordinary general meeting, to be held at Winchester House, Old Broad-street, London, E.C., on Thursday, the 23rd inst., at 12 o'clock:—

The total earnings for the period amount to £82,815. 11s. 11d., as against £80,338. 18s. 3d., an increase of £2,476. 13s. 8d. over the half-year to December 31, 1893. The working expenses amount to £36,403. 17s. 3d., against £35,592. 8s. 10d., an increase of £811. 8s. 5d. Including the amount brought forward from June 30, 1894 (£5,630. 6s. 7d.) and the dividend received upon the shares held in the "Platino" Company, the balance to the credit of the revenue account is £56,660. 3s. 9d., from which has been deducted £11,601. for debenture interest, and £5,000 for the debenture redemption fund, leaving £40,059. 3s. 9d., of which £8,000 has been placed to the reserve fund. The Directors now recommend the payment of 6s. per share, free of income tax, for the half-year on the Ordinary shares, making, with the dividend paid in November last, £3 per cent. for the year, leaving a balance of £2,846. 1s. 9d. to be carried forward. In the case of shares which have been divided into "Preferred" and "Deferred," the 6s. per share now recommended will be payable, viz., 4s. 6d. to the "Preferred" shareholders (making up the full dividend of £5 per cent. on these shares for the year 1894) and 1s. 6d. per share to the "Deferred" shareholders.

The accounts include £5,000, an estimated income derived from the traffic over the Pacific and European Company's line between Buenos Ayres and Valparaiso, from the date of the opening of the line up to December 31st last. Debentures amounting to £15,000 have been drawn and paid off at par. Dividend warrants will be posted on the 24th inst.

This Company's action against the Brazilian Submarine Company, referred to in previous reports, was heard on March 8th last before Mr. Justice Romer, and decided on all points in the Company's favour. The £6,000 per annum is now being paid by the Brazilian Submarine Company.

The Brazilian Government have passed a law through the Chambers and the Senate authorising the Government to acquire this Company's undertaking, and, in this connection, the Company's representative in Rio de Janeiro has been at home for consultation with the Board. He is now on his way back with full instructions for the arbitration which is required in Brazil under the Concession. The Board has every reason to believe that the Company will receive fair treatment at the hands of the Government.

Mr. W. S. Andrews and Mr. D. H. Goodsall seek re-election as Directors, as do the auditors, Messrs. Turquand, Youngs, Bishop and Clarke, and Messrs. Deloitte, Dever, Griffiths and Co.

West India and Panama Telegraph Company (Limited).

The report of the Directors of this Company for the half-year ended December 31st last, to be submitted to the thirty sixth ordinary general meeting, to be held at Winchester House, Old Broad-street, London, E.C., on Wednesday, May 22nd, at 12 o'clock, is as follows:—

The amount to credit of revenue is £33,243. 4s. 4d., against £34,265. 6s. 4d. for the corresponding half-year of 1893, and the expenses have been £23,613. 14s. 8d. against £22,602. 8s. 3d. for the same period in 1893, leaving a balance of £9,629. 9s. 8d., which, with £2,850. 3s. 11d. brought from last account, makes a total of £12,479. 13s. 7d., with which it is proposed to deal as follows:—

First Preference shares—			
Dividend, 6 months to December 31st, 6s. per share	£10,368	18	0
Second Preference shares—			
Dividend, 6 months to December 31st, 6s. per share	1,400	14	0
Balance to current half-year's account	710	1	7
	£12,479	13	7

The traffic receipts for the six months show a decrease of £1,948. 17s. 5d., as compared with the corresponding period, and those for the current half-year show no improvement. The cost of repairs to cables during the half-year amounted to £10,501. 2s. 10d., being £951. 16s. more than that for the corresponding period. This increased expenditure is due to the number of interruptions and to the length of new cable required to repair them. Owing, however, to the Company's duplicated system these interruptions have caused no loss of traffic, every station having been maintained in constant communication.

The contract with the French colony of Guadeloupe expired on December 31st last, and that colony's subsidy of £2,000 per annum was from that day transferred from this Company to the Compagnie Française des Cables Télégraphiques. It will be remembered that a similar course was adopted under orders of the Home Government by the French island of Martinique in March, 1890. This Company has thus been deprived of a revenue of £4,000 per annum, after performing the telegraphic service of those colonies for upwards of

Digitized by Google

20 years, and their subsidies have been transferred to a competitor possessing only a single line of cable connecting them with Cuba. This loss of revenue, combined with the declining traffic and the reductions made in subsidies by two British colonies in 1893, has rendered the payment of any dividend on the Ordinary shares impracticable this half-year. The duty of maintaining an efficient service, and of fulfilling the unprecedented obligation of providing news to the colonies, is one that, in existing conditions, it is impossible to perform with due regard to the equitable claims of the capital employed in the enterprise.

The Company's second repairing steamer "Duchess of Marlborough" is still lying up in London, the "Grappler" having satisfactorily dealt with all repairing operations in the West Indies.

Mr. Henry Holmes seeks re-election as Director, as do the auditors, Messrs. Deloitte, Dever, Griffiths and Co.

NEW COMPANIES, STATUTORY RETURNS, &c.

ACETYLENE ILLUMINATING COMPANY (LIMITED).—This Company was registered on May 9th with a capital of £21,900, in £1 shares, to enter into an agreement with Samson Fox for the acquisition of certain licences and privileges, and to carry on the business of constructors and users of electric smelting and other furnaces, machine builders, engineers, purchasers of and dealers in chemical and mineral substances and products of all kinds, and manufacturers of all kinds of apparatus necessary for carrying on the manufacture and disposal of materials and substances produced or formed by means of heat generated electrically.

CAMBRIDGE SCIENTIFIC INSTRUMENT COMPANY (LIMITED).—This Company was registered on May 11th, with a capital of £10,000, in £5 shares, to purchase and take over the business now carried on at Cambridge by Horace Darwin, under the style or firm of the Cambridge Scientific Instrument Company, to carry out an agreement with the said Horace Darwin, and to carry on the business of mechanical and electrical engineers and manufacturers of and dealers in scientific and electrical instruments.

DE MARE INCANDESCENT GAS LIGHT SYSTEM (LIMITED).—This Company was registered on May 8th with a capital of £100,000, in £1 shares. Included in its objects are the carrying on of the businesses of an electric lighting and power company, mechanical engineers, &c.

D.P. BATTERY COMPANY (LIMITED).—This Company was registered on May 11th, with a capital of £10,000, in £1 shares, to carry into effect an agreement between Walter C. Johnson, of "The Dignaries," Westcombe Park, Blackheath, Kent, and Bernard Drake and John M. Gorham, electrical engineers, of 66, Victoria-street, Westminster, London, S.W., to carry on the business of making, buying, selling, repairing, maintaining, and otherwise dealing with accumulators, or storage batteries, and accessories for electrical purposes, and of making, buying, selling, and dealing in machinery, materials, stores, appliances and apparatus of every description applicable for, or in connection with, the supply or use of accumulators or secondary batteries, or used for the accumulation or distribution of electrical force. The subscribers, with one share each, are: Walter C. Johnson, Mrs. W. C. Johnson, Bernard Drake, John M. Gorham, Alfred C. Read, Edwin G. Giller, Mrs. Bernard Drake, and G. A. Hughes. The first Directors are: Bernard Drake, John Gorham and Walter C. Johnson.

ALTRINCHAM ELECTRIC SUPPLY (LIMITED).—The first annual return, to April 11th, has been filed. Of a nominal capital of £50,000, in £1 shares, 25,000 have been taken up, and a call of 10s. per share has been made and paid. The statutory return of the Company ro August 2nd was filed on May 3rd.

ANGLO-PORTUGUESE TELEPHONE COMPANY (LIMITED).—The annual return, to April 11th, has been filed. The nominal capital is £75,000, in £1 shares, of which 50,000 have been taken up and issued as fully paid. The total amount of shares for which share warrants, comprising 10 shares each, are outstanding is £4,020.

W. T. HENLEY'S TELEGRAPH WORKS COMPANY (LIMITED).—The annual return, to April 5th, has been filed. The nominal capital is £100,000, divided into 7,000 Ordinary and 3,000 Preference shares of £10 each. All of these have been taken up, and the full amount called. £99,940 has been received.

ROGERS' ARC LAMP COMPANY (LIMITED).—The statutory return to April 19th has been filed. Out of a nominal capital of £20,000 in £5 shares, 3,007 have been taken up, and of these 3,000 have been issued as fully paid.

ROSE AND BIRD (LIMITED).—The statutory return to April 22nd has been filed. Of the nominal capital of £3,000 in £1 shares, 2,184 have been taken up, and 1,000 shares have been issued as fully paid. The full amount has been paid on the remainder.

ROWLAND BARNETT AND CO. (LIMITED).—The statutory return to August 2, 1894 has been filed. Out of a capital of £20,000, in £1 shares, 5,009 have been taken up, and 5,000 of these have been issued as fully paid to Rowland H. Barnett, of Brighton Grove, Newcastle-upon-Tyne. The full amount has been paid on the remainder. The first annual return to April 24th has also been filed. 5,000 shares have been allotted as fully paid to Rowland H. Barnett as the purchase money of the business, which, according to a remark on the return, practically belongs to him, and is now being carried on by him with his private moneys.

SALT LAKE AND OGDEN GAS AND ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company to February 9th has been filed. Out of the capital of £300,000, in £1 shares, 260,000 have been taken up and issued as fully paid.

SCARBOROUGH ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of this Company to April 2nd has been filed. Out of a capital of £50,000, in £10 shares, 2,681 shares have been taken up, and on each of these £9 have been called.

SCOTTISH HOUSE-TO-HOUSE ELECTRICITY COMPANY (LIMITED).—The annual return of this Company, to December 31st, was filed on May 3rd. No meeting was held in that year, as business has not yet been started. The nominal capital of £100,000 is divided into 19,900 Ordinary and 100 Founders' shares of £5 each. All the latter have been issued as fully paid, and the full amount has been called on the Ordinary resulting in the receipt of £3,758.

SOUTHAMPTON ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of this Company to April 22nd has been filed. The nominal capital is £30,000, divided into 4,000 Preference and 2,000 Ordinary shares of £5 each; 50 Preference and 708 Ordinary shares have been subscribed for and allotted, and the full amount called.

SOUTH-WESTERN DISTRICT AND THAMES VALLEY ELECTRICITY SUPPLY COMPANY (LIMITED).—In answer to a request for the filing of the statutory returns of this Company, the solicitors state that the Company has never carried on business, and that its name should be struck off the Register.

ST. MARTIN'S ELECTRICAL MANUFACTURING COMPANY (LIMITED).—The annual return of this Company, to March 12th, has been filed. The capital consists of 100 shares of £5 each, and 45 of these have been taken up. The full amount has been called and paid.

SYNDICATE OF ELECTRICAL ENGINEERS (LIMITED).—The annual return of this Company to March 11th has been filed. The nominal capital is £10,000, divided into 1,900 Ordinary and 100 Founders' shares of £5 each, and 1,007 of the former and all the latter have been taken up. The Founders' have been issued as fully paid, and £4 per share has been called on the Ordinary.

UNIVERSAL ELECTRICAL FITTINGS COMPANY (LIMITED).—The statutory return to April 3rd has been filed. The whole nominal capital of £6,000 has been taken up, and a call of 2s. 6d. per share has been made.

UNIVERSAL ELECTRIC LIGHTING COMPANY (LIMITED).—The statutory return to January 31st has been filed. The nominal capital of £5,000 is divided into shares of 10s. each. Only seven shares were subscribed for and allotted. The first annual return, to May 1st, is also filed. 8,527 shares were taken up, of which 6,000 were issued as fully paid, and the full amount has been called on the remainder.

WARD ELECTRICAL CAR COMPANY (LIMITED).—The annual return, to December 16, 1894, was filed on April 25th. No meeting was held in 1894. The whole nominal capital of £300,000, in £10 shares, has been taken up, and 29,993 of these have been issued as fully paid. The full amount has been paid on the remainder.

WATERHOUSE ELECTRICAL MANUFACTURING COMPANY (LIMITED).—The annual return to December 31st was filed on the 6th inst. The nominal capital is £20,000, divided into 1,000 Vendors', 800 Ordinary, and 200 Preference shares, of £10 each. All the Vendors' shares have been taken up and issued as fully paid; 285 Ordinary and 53 Preference shares have been allotted and the full amount called.

WATERHOUSE ELECTROMETRIC SYNDICATE (LIMITED).—The annual return to January 14th has been filed. The nominal capital is £20,000, divided into 1,000 Vendors' and 1,000 Ordinary shares of £10 each. All the former have been taken up and issued as fully paid; 308 Ordinary shares have been allotted and the full amount called and paid.

WEST INDIAN DEVELOPMENT COMPANY (LIMITED)—(Supplying electricity to the City of Bridgtown, in the Island of Barbados).—The annual return to January 1st has been filed. Of a capital of £5,000, in £1 shares, 4,070 have been taken up, and of these 4,000 have been issued as fully paid.

WOODFIELD SYNDICATE (LIMITED).—The annual return to April 10th has been filed. The whole nominal capital of £12,000, in £1 shares, has been subscribed for and allotted, the full amount called and paid.

CITY NOTES.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended May 12th were £832, as against £905 in the corresponding period of 1894, being a decrease of £73. The total receipts for the half-year amount to £17,815, against £17,305 for the corresponding period of 1894, an increase of £509.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—The Directors of this Company have resolved, subject to audit, to recommend to the shareholders at the approaching general meeting a dividend at the rate of £1. 10s. per cent. per annum, less income tax, for the year ended March 31, 1895.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 12th inst. amounted to £1,159. The amount for the corresponding week last year was £824.

REUTER'S TELEGRAM COMPANY (LIMITED).—The thirty-first ordinary general meeting of the shareholders of this Company will be held on Wednesday, the 29th inst., at noon, at the offices, 24, Old Jewry, E.C., for the reception of the Directors' report and balance sheet.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended May 10th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,793.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 888. [No. 4. Vol. XXXV.] FRIDAY, MAY 24, 1895. PRICE SIXPENCE.

NOTES.

We would call the attention of our readers to the evidence given on Tuesday last by Mr. James Staats Forbes before the Select Committee on the Telephone Service. It is undoubtedly the best contribution to the matter under inquiry that the Committee has so far elicited. The statement of the President of the National Telephone Company was, of course, a piece of special pleading, and a remarkably fine specimen of the art; but it was instructive, interesting, lucid, and to the point, and should serve as a wholesome corrective to the many *ex parte* assertions which have preceded it. There has been far too much comparison of the charges and service of the National Company with those in happy lands where Post Office and patent royalties are non-existent, and way-leaves give no trouble, where wages are low and material cheap; the charges made and the service rendered in countries more or less comparable with our own, such as America, Germany, and France being conveniently ignored.

We cannot but commend the wisdom of the Postmaster-General in granting the Committee asked for by Mr. Kearley to inquire into the alleged grievances of the postal- and telegraph servants, and especially his choice of men outside the service to institute the inquiry. It is not particularly flattering to telegraphists to be lumped in with letter carriers for a purpose of this kind; but it may be useful, if only to make clear by comparison the relative pay and privileges of these two very different classes of civil servants. The public will probably find out that the postmen have little or nothing to complain of; while Mr. Morley will discover that the telegraphists have greater grievances than he has been led to suppose. It is hoped the last-named body of men will not spoil their case by asking unreasonable and impossible concessions which are granted to no other branches of the Civil Service. Of the several substantial hardships of which the telegraphist complains, not the least is the one denying him redress because of the "shrinking revenue" of the service to which he is attached. He knows perfectly well that the alleged shrinkage is a fiction, and, rightly or wrongly, regards it consequently as a mere excuse for rejecting his claims in order that the insatiable demands of his more powerful comrades of the postal service may be satisfied.

The clause inserted this year by the Board of Trade in the Strand and other metropolitan Orders to which attention was called in the House of Commons on Monday, although undoubtedly excellent in intention, seems to us to go perilously near to being *ultra vires*. The clause in question provides that the Local Authority shall have the option of purchasing the undertaking, not at the end of 42 years from the passing of the Confirmation Act, as is usually the case, but after "a period of forty-two years from the twenty-sixth day of August one thousand eight hundred and eighty-nine." The reason for this provision, Mr. Bryce informed the House on Monday, was that "the Board of Trade have held that it is in the interest of London that the power of purchase by the Local Authority shall as far as possible operate at the same date over the whole of the metropolis." In view of the pertinacious opposition offered by the North Metropolitan Tramways Company to the acquisition of its undertaking by the London County Council, under the terms of the Tramways Act of 1870, and its absurd contention in connection with the taking over of its lines piecemeal, this step of the Board of Trade shows shrewd foresight.

Considering the efforts that were expended in securing the deferment of the day of purchase from 21 to 42 years, it has always seemed to us to savour of weakness and to tend to reckless finance to whittle away the advantage so secured in order to gain the favour of Local Authorities. But in many instances it is doubtless a case of Hobson's choice for the promoters of Electric Lighting Orders, as Section 2 of the Act of 1888 undoubtedly gives Local Authorities full power to drive a hard bargain. But for a Government department, be its intentions of the highest order of excellency, entirely on its own authority, as implied by Mr. Bryce, to curtail a certain period deliberately laid down in an Act of Parliament is, to our mind, a very high-handed proceeding. If such curtailment be to the public interest, well and good; but those who suffer for the public weal should be reasonably compensated. An alteration in the terms of purchase by mere fiat of the Board of Trade would not, of course, be tolerated by the Local Authorities. But electric light companies, on the other hand, are expected to indulge in "sombre acquiescence" when a Government department legislates against them *pro bono publico*.

The Bureau de Contrôle des Installations Électriques, the main objects of which are set forth in another column, is a very characteristic French institution. To English minds a corporate body which openly admits that it owes its existence

Digitized by Google

to the numerous accidents caused by defective wiring, and announces it chief *raison d'être* to be the testing of house wiring and the affording of information concerning the safe working of electric lighting plants, would seem to be tolerably well calculated to frighten intending consumers. However, across the Channel they not unnaturally prefer any cure to none at all, and we might do well to consider what sort of English equivalent would meet the exigencies of the case at home. Since the interests of the electric supply companies and the fire offices are identical, it is to be regretted that instead of each supply company and each fire office drawing up its own set of rules, differing only in unimportant details, they do not devise a common set of thoroughly practical regulations, and secure their enforcement. This might not have been possible in the early days of electric supply, when it was not politic nor even, perhaps, possible for struggling companies to refuse to connect up a large customer merely because he had been short-sighted or unfortunate enough to get his wiring done on the cheap. In this year of grace, however, the supply companies can afford to be a little more independent. To suggest to electric light consumers that they should join a sort of society for mutual protection and safety would no doubt sound to some of them rather alarming; but since periodic inspection of wiring is even more necessary in the interests of safety and convenience than perfunctory visits by overworked fire-office officials before houses are connected up, the meter inspectors of the supply companies might very well be made to do a double duty, and, armed with an ohmmeter and a dose of common-sense, might make a rough, but nevertheless reliable, test of the wiring. In any case, however, the householder would have to put up with the fuss of having all the lamp bulbs removed from their sockets and all the switches turned on. To avoid giving unnecessary alarm and trouble these tests might invariably be carried on during the out-of-town quarter.

Even in France the operations of the Bureau de Contrôle do not appear to have proved very extensive, though perhaps under the new management this state of things may be altered. Either the standard set by the Bureau must be extremely high or jerry wiring must be even more rampant in France than in this country; and, what is worse, on the increase. In the first year of the existence of the Bureau it will be observed that some 60 per cent. of the installations inspected were reported as being defective from one cause or another, whilst in the second year the figure was nearly 90 per cent. This would give cause for decided uneasiness were it not that in matters of this kind the personal equation of the inspector is all important, especially if anything and everything has to be done to his satisfaction, and he is not bound down within the four corners of explicit regulations.

Mr. Campbell Swinton has been "amang" the electrical supply companies of London, with a hot-wire recording voltmeter, "takin' notes." He has been the round of the mains, and day by day has tapped them to find out what sort of continuity there is in the maintenance of their electrical pressure. The story told by the hot-wire instrument, and we doubt not it is a true story, so far as it goes, is embodied in an instructive set of diagrams, which we publish this week, together with some explanatory remarks by Mr. Swinton.

Comparisons, it has been said, are odious; but we hope that none of the supply concerns, whose lapses from the ideal are embodied in these researches, will experience any odium from the seeming irregularity of the electrical pressure supplied by them. It is rarely that comparisons such as these bring out the actual relative merits of the competitors in their true light; and we apprehend that no one will recognise this fact better than Mr. Swinton himself. It is to be regretted that he has given us such scant information as to the exact position on each network of mains of his tell-tale voltmeter. So much depends on this position. If the voltmeter happen to be quite close to a feeding point in one case, and at a distance from a feeding point in another case, this alone would produce a difference in the record, although, of course, if the distributors were up to Board of Trade requirements the difference should not be very marked.

In our footnote to Prof. Unwin's lecture, on page 80 of our last issue, we made a comment which was based upon a misapprehension of Prof. Unwin's remarks on the expansion of steam. The isothermal for superheated steam is $pv =$ constant, and for saturated steam it is $p =$ constant; so that when Prof. Unwin says that "the actual expansion curve of an engine is much more nearly an isothermal than an adiabatic, because the steam receives heat from the cylinder wall," he refers to a case where the influx of jacket heat is so great as to cause the expansion line to rise considerably above the corresponding isentrope for adiabatic expansion. As a matter of fact, however, the effect of the jacket is rarely, if ever, so pronounced as to cause the steam to expand nearly isothermally; and, as Prof. Unwin observes in a communication made to us, it is more correct to speak of the expansion as "nearly a hyperbola" in the case of most, if not all, jacketed engines.

There have been a great many primary batteries invented lately, and as one of the chief *raisons d'être* of a primary battery is to exhibit remarkable properties, the electrical world has been treated to a surfeit of "wonders." Recently M. Renault, of Paris, has devised a neat little primary battery, which we should judge would be serviceable in experimental work. There did not appear to be anything wonderful about this battery until a contemporary discovered that gelatinous silica, one of the constituents of the cell, possesses "the remarkable property of absorbing 60 times its volume of water." But the wonder of the thing vanishes when we remember that gelatinous silica will not do this without, like Sam Weller's maternal parent, "swelling wisibly"; or, when we state the matter in another way and say that water has the power of dissolving one-sixtieth of its volume of this gelatinous compound.

Electrical Bills in Parliament.—The London, Walthamstow and Epping Forest Railway Bill was read a second time in the House of Commons on Monday.

Digitized by Google

Society of Arts Conversazione.—This *conversazione* will be held at South Kensington on Wednesday evening, June 19th.

Cable Interruptions:

	Date of Interruption.	Date of Repair.
Latakia—Cyprus	Nov. 27, 1894.	May 22, 1895.
Gibraltar—Tangier	April 24, 1895.	May 16, 1895.

Electric Railway to Vesuvius.—Messrs. Thomas Cook and Son, the owners of the railway up Vesuvius, propose to put down an electric railway between Naples and the funicular railway terminus.

Royal Institution.—The Friday evening discourse on June 7th will be by Prof. Alfred Cornu, F.R.S. This discourse will be delivered in French, and the title is "Phénomènes Physiques des Hautes Régions de l'Atmosphere."

North Sea-Baltic Canal.—At the opening of this canal the harbour of Kiel, right down to the mouth of the canal at Holtenau, will be lit by electric light, as also the extraordinary marquee which is being made to the designs of the Emperor.

Northern Society of Electrical Engineers.—Mr. John Darney has been compelled to resign his position as hon. secretary of this Society, owing to his removal from Manchester, and the position has been taken by Mr. J. Vincent Swindells.

Meeting of the Verband Deutscher Elektrotechniker.—It is announced that the third annual meeting of this Association will be held on July 4th to 7th, at Munich, and not, as formerly stated, at the end of June. During the meeting of the Association the Ohm memorial will be unveiled.

Street Lighting by Arc and Glow Lamps.—A rather interesting example of street lighting came into operation last week at Wilda, near Posen. The system is a combination of arc and glow lighting, and was laid down by the Helios Company. Forty arc lamps provide the necessary illumination up to 11 p.m., after which hour glow lamps are used, taking their current from a battery.

Alternators.—In connection with the Paper recently read before the Elektrotechnischer Verein by Herr von Dolivo-Dobrowolsky, and published in our last issue, we may say that we have been shown by a well-known English electrician the drawings of a new type of alternator somewhat on the lines of those described by Herr Dobrowolsky, of which more may be expected to be heard as soon as the experimental machine now in course of construction has been completed and tested.

The Fluid Theory of Electricity.—The fluid theory of electricity, notwithstanding its lack of solid basis, apparently still holds its own in America. A New York contemporary, of recent date, contains the following announcement:—"Manchester, N.H.—The contract for furnishing electricity for the new electric road stipulates that *the fluid* shall be ready to be turned on on July 1st." The winters of New Hampshire are, we believe, somewhat severe, and it is to be hoped that the fluid will not freeze.

Liverpool.—Another step has been taken by the Lighting Committee of the Liverpool Corporation towards the acquisition of the plant and rights of the Liverpool Electric Supply Company, this being the approval of the draft of the agreement for the purchase of these at the price of £400,000. The agreement having been approved by both parties, the next step will be to apply to Parliament for powers to carry out the arrangements agreed upon, and it is expected this authority will be secured during the present session.

A Secondary Battery Patent.—Mr. J. Wilson Swan's patent, No. 2,272 of May 24, 1881, intituled "Improvements in Secondary Batteries or Apparatus for Storing or Conserving Electricity," legally expires to-day. In *The Electrician* of January 18th last, on page 339, we published abstracts of all the secondary battery patents expiring this year. The Swan claim was as follows:—Constructing the plates of secondary batteries or apparatus for storing or conserving electricity with cells, corrugations, grooves, or interstices substantially as and for the purpose hereinbefore described.

The Illumination of Streets by Electricity.—In an article on this subject in the May number of the *Engineering Magazine*, Mr. Franklin Leonard Pope states that the first attempt to illuminate a town by electricity was made at Wabash, Ind., in March, 1880. Arc lamps were used, two being placed upon the tower of the court house and two more on a mast erected for the purpose. The trial run was witnessed by hundreds of visitors from all parts of the country. The plant, consisting of four lamps and the dynamo, is said to have originally cost £3,600. It was operated continuously for six years, after which it was taken down and ultimately sold for £6 as a historical curiosity.

Steam Engines (Persons in Charge) Bill.—This Bill came to an untimely end on Wednesday, in the Select Committee to which it was referred. In accordance with an understanding arrived at when the Bill was read a second time, Mr. John Wilson (Durham) proposed the exclusion of locomotive engines, the engines of steamboats, and agricultural engines from the scope of the Bill. On the division of the Committee, seven voted for the provision and seven against, and the Chairman gave his casting vote in its favour. Mr. Brunner then moved that the Committee should not proceed any further with the Bill, and this motion was carried, after a sharp discussion, by nine to four. The Bill will consequently not be reported to the House.

Electricity in Australian Mines.—At Hillgrove, in New South Wales, an electric transmission of power plant has been put down for the working of several of the mines of the district. The water of the Gyra river is employed to the extent of about 850 H.P. A canal 1½ miles in length leads the water to a large reservoir. From thence it is carried in pipes, and in a distance of 900ft., 500ft. fall is obtained. The power-house contains three Pelton water wheels of 250 H.P. for driving the power generators, and two ditto of 50 H.P. each for lighting purposes. It has been ascertained that while steam-power at Hillgrove cost £49 per horse-power per annum, owing to the difficulty of obtaining fuel, the electric power only costs £30 per horse-power per annum, or a saving of nearly 40 per cent.

Hydro-Electric Supply.—The Compagnie Hydro-Électrique d'Anvers, which was started some time ago with a considerable flourish and a capital of £110,000 to work an electric supply station on the Van Rysselberghe hydraulic system, has just issued its first annual report. By this it will be seen that the system of hydraulically driving dynamos, situated in various sub-stations up and down the town, has not been so successful as anticipated. The entire capital has been expended, and though there are 248 consumers, the balance-sheet shows a deficit of £1,713. The management frankly admits that the hydro-electric system is very much handicapped, and cannot compete with other electrical systems. Notwithstanding this, the Directors propose to continue the experiments on an extensive scale, and intend to take up a new loan of £72,000.

Electric Mail Cars in America.—The post office officials in Washington, says the *Street Railway Gazette*, are greatly interested in utilising street railway systems for the rapid distribution of letters, and they are now extending the service. Electric mail cars have just made their appearance in Boston, where the system has been organised on a much more liberal scale than has yet been attempted elsewhere. Eight mail cars have been equipped. The preliminary trials that were made by the post office authorities to determine the possibilities of the new system indicated that the saving in time would be very considerable. Within a comparatively short time mail cars will be operated on the street railway tracks in Chicago and Philadelphia, and plans for the extension of the system to New York are under consideration.

The "Holland" Submarine Electric Boat.—The United States Navy Department, says the *Electrical Engineer* of New York, has contracted with the John P. Holland Torpedo Boat Company, of New York, for a submarine torpedo boat, to cost $150,000. The dimensions of the boat are: Length, 80ft.; diameter, 11ft.; displacement, 138·5 tons. The boat is to be completed in every respect by March 26, 1896. She is to have a speed of not less than 15 knots when in a light condition, 14 knots when awash, with a minimum endurance of 12 hours at these speeds, using only steam power, and 8 knots an hour when the vessel is completely submerged, using electric power, with a minimum endurance of 6 hours at this speed. Below

Digitized by Google

13½ knots for the light condition, or 12½ knots for the wash condition, or 6½ knots when submerged, the Secretary of the Navy may reject the vessel, or accept her at a reduced price.

Overhead Wires.—In answer to a question by Mr. Weir in the House of Commons, the President of the Board of Trade stated that private electric lighting companies having statutory powers were under obligations similar to those imposed on Local Authorities, and were also prohibited from using overhead wires without the consent of the Board of Trade and the Local Authority. Private electric lighting companies not having statutory powers were subject to regulations for the protection of the public safety prescribed under the provisions of the Electric Lighting Acts, 1882 and 1888. Although the use of overhead conductors were not prohibited by those Acts, urban authorities under the Public Health Act of 1890 were empowered to make regulations for the prevention of danger or obstruction to the public from wires stretched over, along, or across any street.——It is as well that this fact should be widely known, and the powers granted to urban authorities under the Public Health Act of 1890 made vigorous use of to prevent the disfigurement of rich residential districts by ugly cables flung across roads at all possible angles to the vertical and horizontal, and occasionally secured to huge transatlantic-looking poles.

The Size of Transformer Chambers.—At the weekly meeting of the London County Council, held on Tuesday, the Highways Committee reported that on February 12th last the Council directed that it should be suggested to the Board of Trade that in the Orders for which applications had been made that year by the County of London and Brush Provincial Electric Lighting Company in respect of (*a*) Battersea, (*b*) Newington, and (*c*) St. Olaves districts the following words should be inserted :—"Provided always that nothing in this Order shall be held to authorise the undertakers to construct in or under the surface of any public street or place chambers or receptacles for transforming apparatus of greater span than 3ft. and more than 2ft. 6in. in depth." With regard to the applications, the first two had been withdrawn, and with regard to the last, the Board of Trade had intimated that they thought it undesirable to limit in the Order (which can only be amended by a further Order) the precise size of transforming chambers, and was therefore unable to insert the clause suggested by the Council. Having regard to the opinion of the Board of Trade, the Committee did not see that anything further could be done with reference to that Order.

Electrolytic Zinc Works.—In the large pyrites mines of Sicilia and Sigena, at Grevenbrück, Westphalia, the pyrites obtained contains a large proportion of zinc. The pyrites is first sent to a chemical works in Mannheim, on the Upper Rhine, where it is used in the manufacture of sulphuric acid by the usual process. The residue is then shipped to the new electrolytic zinc works which Messrs. Sicilia and Sigena have built on the Rhine at Duisburg-Hochfeld, in the neighbourhood of some of the largest blast furnaces in Germany. Here it is unloaded by electric cranes. The material is then lixiviated, and the residue roasted with salt to obtain the purple iron ore. The new residue is again lixiviated, and the zinc is then electrically deposited from the lye. The zinc thus obtained is said to be much purer than the best zinc hitherto obtainable, and it commands a high price. The purple ore is sold to the neighbouring blast furnaces. The works have only been in operation a few months. At present they deal with an average of 30 tons of the residue from the sulphuric acid works per day; this contains 10 per cent. of zinc, all of which is recovered. The works when completed will be capable of dealing with four times this quantity—*i.e.*, of producing 12 tons of zinc per day. The cost of sending the ore from one factory to the other is very small, as both the chemical works at Mannheim and the electro-chemical works at Duisburg-Hochfeld lie close to the water's edge.

Electric Traction Disturbance of Telephone Lines at Hobart.—In an appendix to the second report of the Committee appointed at the Postal and Telegraph Conference held at Hobart in 1892, for the purpose of drafting a set of electric light and power regulations, Mr. R. Henry, Superintendent of the Tasmanian Telegraphs, describes the disturbances caused on the Hobart telephone system by the running of the electric tramway in that city. According to Mr. Henry, there is a steady humming sound in the telephones, which, however, is not sufficient to destroy conversation, and is distinctly traceable to induction pure and simple. Occasionally there is a musical sound, difficult to describe, but resembling a steam siren at a great distance. This sound always commences at a comparatively low pitch and gradually ascends until it finally disappears as if the vibrations were too rapid to be rendered audible. Its duration extends over a few seconds only. Yet another disturbance is noted by Mr. Henry—namely, a rasping sound very much like broken contacts with a battery through a telephone receiver. This would appear to be caused by leakage currents and irregular contacts with dirty rails. The most annoying trouble is, says Mr. Henry, the dropping of the shutters at the exchange, long lines suffering more than short wires. The greater the number of cars in use the greater the number of shutters affected. Occasionally when there is short-circuit on the line 250 out of 400 shutters go down. Mr, Henry finally reports that the resistance of the earth return seems to be more than it should be (0·4 ohm—0·23 ohm).

Electrical Trade Section.—The following paragraph relating to the Electrical Trade Section appears in the thirteenth annual report of the London Chamber of Commerce presented at the annual general meeting on Tuesday :—

"Twelve meetings of this Section and its committees were held during the year. The Section had under its consideration the advisability of the industry as a whole lending its support to the Antwerp Exhibition, and a circular was issued with the object of ascertaining what support was likely to be forthcoming, to which, however, there was no practical response. Early in the year the Traction Committee had an interview with the officials of the Board of Trade with reference to the draft of the Protective Powers Regulations, and a set of rules was ultimately issued which were believed to be satisfactory to the various interests concerned. Subsequently the Traction Committee made representations to the Postmaster-General with reference to what is known as 'the Postmaster-General's clause,' and satisfactory assurances as to the due protection of the traction interests were obtained. Special attention was given by the section to the rating of electrical works, a small Committee being appointed to deal with the matter, and a large amount of evidence as to the anomalies of the present system was obtained. The Section took joint action with the Engineering and Allied Trades Section in regard to the question of Light Railways as raised by the Board of Trade. Steps were also taken by the Section to bring their views before the Board of Trade Inquiry as to the placing of transformer chambers in the public streets, and a resolution was passed expressing the opinion that such chambers would not be dangerous to the public, and could be constructed so as to form no serious obstacles to the future use of the streets for other necessary purposes. The decision ultimately arrived at by the Board of Trade was considered favourable to electrical companies."

Two-Phase Transmission of Power Plant in America.—An installation of some interest has been erected at Fitchburg, Mass. The plant consists, says the *Electrical Engineer* of New York, of one 300-kilowatt Westinghouse two-phase generator, of the "plus two" type; that is, it has two more teeth on the armature than there are poles in the field. The current is generated at a potential of 2,250 volts. A 15-H.P. multipolar Westinghouse exciter is used, which is of sufficient capacity to excite two 300-kilowatt machines, as a second machine will be erected in a short time. The exciter runs at 1,150 revolutions, and is driven separately by a small Pelton wheel. The generator is direct connected to six Pelton double-nozzle 28in. water wheels, all on the same shaft, running at 375 revolutions. Water is supplied from the Wanoosnoc River under a 130ft. head at the rate of 2,000 cubic ft. per minute. The flow of water is controlled by a Doolittle governor, which consists of three separately actuated gears, one having large inertia, revolved by a separate water motor, and thus kept at constant speed, a second gear, driven by the generator shaft, and between these two is the third gear, connected by means of pinion and rack with levers that actuate butterfly valves controlling the admission of the water to the wheels. At present, all the power generated is used by the Simonds Manufacturing Company, whose works are about two miles from the power house. The transmission circuit consists of four stranded conductors. each having a cross-section of 0·4 sq. in. The wire is covered with weather-proof insulation, and carried on special poles, The current is transformed from 2,150 to 220 volts by means of two 100-kilowatt Westinghouse oil transformers, and supplied to 11 Tesla motors ranging from 75 to 7½ H.P.

ATMOSPHERIC ELECTRICITY.*

BY PROF. A. SCHUSTER, F.R.S.

It is hardly possible to imagine that the first experimenter who obtained an electric spark sufficiently strong to produce a sensible sound should not at once have been struck with the fact that he was in the presence of thunder and lightning on a small scale. We find, indeed, in various writings from the early days of electrical machines, a number of suggestions that the thunderstorm was an electrical phenomenon, but the merit of having perceived that a direct experiment was needed to prove what so far was only a guess belongs to Benjamin Franklin. In an article entitled "Opinions and Conjectures Concerning the Properties and Effects of the Electrical Matter, arising from Experiments and Observations made at Philadelphia, 1749," the following passage occurs :—

"To determine the question, whether the clouds that contain lightning are electrified or not, I would propose an experiment to be tried where it may be done conveniently. On the top of some high tower or steeple, place a kind of sentry-box, big enough to contain a man and an electrical stand. From the middle of the stand let an iron rod rise and pass bending out of the door, and then upright 20ft. or 30ft., pointed very sharp at the end. If the electrical stand be kept clean and dry, a man standing on it, when such clouds are passing low, might be electrified and afford sparks, the rod drawing fire to him from a cloud.

"If any danger to the man should be apprehended (though I think there would be none), let him stand on the floor of his box, and now and then bring near to the rod the loop of a wire that has one end fastened to the leads, he holding it by a wax handle ; so the sparks, if the rod is electrified, will strike from the rod to the wire and not affect him."†

The experiment suggested by Franklin was successfully performed in Marly (France) by D'Alibard, on May 10, 1752,‡ in London by Carter, in Spital-square, on July 20, 1752, and by Wilson, in Chelmsford, Essex, on August 12th of the same year. Franklin himself describes having used a kite in Philadelphia in a letter dated October 19th, but he does not give the date of his observations. But this must be supplied in some passage which I have not been able to find, for Rosenberger§ mentions that it was done in June.

Franklin's disbelief in the dangerous character of the experiments must have received a severe shock when he heard of the death of G. W. Richmann, who, in the year 1753, was killed by an electric discharge drawn from the clouds by means of a kite.

The thunderstorm is the most impressive effect in atmospheric electricity, though it is rivalled in beauty by the aurora and in interest by the many phenomena of daily occurrence, which are only made perceptible to us by proper instruments. In a lecture delivered before this Institution on May 18, 1860, Lord Kelvin described the delicate electrical appliances constructed by him for the more accurate observation of atmospheric electricity. The problems there for the first time clearly stated, gave a powerful and still lasting impulse to its scientific investigation, and though no decisive answer can be given to all the questions raised in that lecture, recent researches have brought us somewhat nearer to their solution.

Observations which may be made every day and at every place have shown that the earth is electrified, whatever the weather may be. In the language of the older theories, which we cannot as yet altogether abandon, we say that the earth is covered with negative electricity, or, in modern phraseology, we express the same idea by the statement that we move about in an electrified field, that electric lines of force stretch through the air from the ground, from our bodies, and everything which is exposed to the sky overhead. The strength of this electric field is not at all insignificant. If we wish to produce it artificially between two parallel plates kept at a distance of one foot, we should have to apply an electromotive force sufficient—and sometimes more than sufficient—to light up the incandescent lamps which illuminate our dwellings. The electric field is comparatively weak in our country, but 50 volts per foot are constantly observed, and 100 volts are not uncommon ; but in dryer climates this amount may be considerably in excess of these figures.

If we fix our minds on the lines of force starting from the surface of the earth, we are at once led to ask, Where is their other end ? Do they curve round and back again to earth ? Do they end in the dust which everywhere surrounds us, or do they reach up to the clouds ? Do they pass through the clouds and end where invisible particles separate the sunset red from the midday blue ? Or, finally, do they leave the earth altogether, and form intangible bonds between us and the sun, the stars, the infinity of space ? These are not idle questions, and we cannot be said to have solved our problem unless some definite answer is given to them. The last-mentioned view, propounded originally by Peltier, and latterly supported by Exner, is the simplest. If we could allow that the earth, once electrified negatively, could remain electrified for ever, the corresponding positive electrification being outside our atmosphere altogether, the chief difficulty of atmospheric electricity would be removed, and the normal fall of potential at the surface would be explained by the permanent negative electrification of the surface.

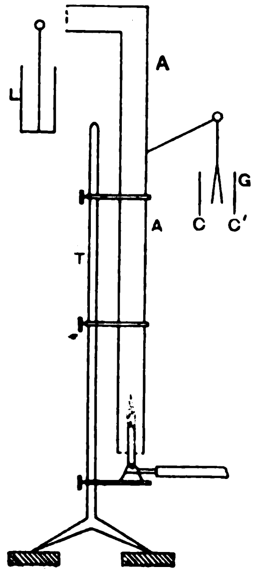

FIG. 1.

Unfortunately, this view, to be tenable, has to assume that the atmosphere is a complete non-conductor to the normal electric stress, and this is known not be the case. We know of several causes which break down the insulating properties of air. If two pith balls are electrified and repel each other, and a match be lit in their neighbourhood, the pith balls come together, showing that they have lost their charge, and consequently that the flame of the match has destroyed the insulating power of air. It is not only the flame itself which conducts, but also the gases rising from the flame.* The following experiment will prove this. In Fig. 1, A represents a metallic tube bent round at the upper end, and containing at its lower end a Bunsen burner in metallic contact with the tube, which is also connected to an electroscope. The tripod T which supports the tube is insulated from the ground by blocks of paraffin. A Leyden, L, on a separate support, is placed so that the knob stands at about the level of the upper part of the tube, which acts as chimney to the flame. The knob of the jar may be a few inches away from the opening of the chimney, and not necessarily in a line with it. The experiment succeeds, although the gases rising from the burner may not come into contact with any part of the jar. The jar is charged, and care

Digitized by Google

must be taken that no fibres of dust attach themselves either to the jar or chimney. I have found it convenient to join a piece of amalgamated zinc to the end of the chimney. Under these circumstances the charge of the jar will be found to leak across to the tube, and the leaves of it will diverge. If, as in Exner's form of electroscope, the leaves, on reaching a certain divergence, discharge by forming a contact with earth-connected plates, C C′, the charging and discharging can be watched for a long time. It will be noticed that the flame, being altogether surrounded by a tube of the same potential, cannot be active in this case, but the conductivity must be due to the gas as it escapes from the chimney.

It follows from these experiments that every fire burnt on the surface of the earth, and every chimney through which products of combustion pass, acts like a very effective lightning conductor, and slowly but surely, any electrification of the surface of the earth would, in consequence, pass into the atmosphere. The peculiar immunity of factory chimneys against damage by lightning, appears from statistics collected by Hellmann in Schleswig-Holstein,* for while 6·3 churches per thousand were struck, and 8·5 windmills, the number per thousand of factory chimneys struck was only 0·3.

Franklin was acquainted with the action of flames; he also discovered that no charge could be given to a red-hot iron ball, a fact which seems to have been forgotten until re-discovered in our own times by Guthrie. Franklin also tried the action of sunlight, but obtained no result. Had he performed the experiment with carefully-cleaned zinc, he would have anticipated one of the most striking of Hertz's discoveries. We now know that a negatively-charged surface will discharge into air when illuminated by strong violet light, and sunlight will be sufficient with specially-sensitive materials. This action has been investigated in detail by Elster and Geitel, who have not, however, succeeded in obtaining results with sunlight acting on such bodies as we know the earth's crust to be made of. So far, then, we have no experimental evidence to include light as an active agent in the phenomenon of atmospheric electricity.

We possess in the electric discharge itself a very powerful, and probably very generally active means of breaking down the insulating power of air. Some of the experiments† which I described some years ago to prove this, were objected to on the ground that it might not be the discharge itself, but the ultra-violet light sent out by the luminosity of the discharge, which was active. The following form of the experiment conclusively shows that the discharge acts independently of light.

In Fig. 2, R represents a Rhumkorff coil entirely surrounded by a metallic box B, which is connected to earth. The terminals of the coil lead to two electrodes inside a metallic tube T, which is also kept at zero potential. This tube is arranged so that a current of air can be blown through it. The air, on escaping through the tube, is made either to impinge on or to pass near a metallic plate connected to a charged electroscope. Under these circumstances, the electroscope is not discharged either by a current of air alone, or by setting the coil going, no air being blown through the tube. But as soon as the air is blown through the spark which the coil is giving, and made to pass into or near the plate C, the electrocope is instantaneously discharged. The experiment succeeds when a plug of cotton wool is inserted at W to stop the action of the dust; but a plug of cotton wool at the other end diminishes the action so much that I am doubtful whether the effect really exists there. But I am, so far, not inclined to believe that the action is due to dust, but rather that the cotton wool acts in increasing very considerably the interval which elapses between the time at which the spark acts and the time at which the sparked air passes out of the tube. The effect may be observed even though the tube L is lengthened by an addition of another piece 3ft. or 4ft. long.

Several phenomena, one of which had been known for a long time, can be explained by the fact that the electric discharge changes the condition of the gas into a state similar to that of gases rising from flames. It is mentioned, for instance, by Faraday that electric sparks are liable to succeed each other along the same path, as it is known that the same holds for lightning flashes, facts which themselves point to a higher conductivity of air along the path of the previous discharge. A curious instance of a similar effect is afforded by lightning conductors, which are sometimes put up to protect overhead leads used for conveying a high-tension current. Owing to the obvious impossibility of connecting the leads directly to earth, a small air gap is interposed, the idea being that the air gap will act as an insulator for the current the leads are intended to carry, but that if during a thunderstorm the potential rises sufficiently high to be dangerous, equalisation may take place through the air gap to earth by means of a small spark. So far, the air gap answers its purpose, but as soon as a spark passes through the gap, it destroys the insulating power of the air, and the main current consequently takes a short-cut through the gap. At Pontresina, in the Engadin, lightning conductors put up in this way are so sensitive that a flash of lightning several miles away causes a small spark by induction, and instantaneously puts out every electric lamp in the town.

If we accept the view that an electric discharge destroys the insulating power of the gas, it follows that the outer regions of the atmosphere must conduct, for we have ample reason to suppose that electric currents are passing continuously through those regions. The aurora borealis in the Arctic regions is, according to Nordenskiold's observations, a permanent phenomenon, and the diurnal changes of terrestrial magnetism show that in our latitudes currents traverse the air above us. However small a conductivity we may assign to the atmosphere under these circumstances, the earth could not remain permanently electrified inside such a shell of partially conducting gases. Lord Kelvin drew the same conclusion in his Royal Institution lecture—that gases at much-reduced pressures cease to insulate. We may leave it an open question whether the normal electric stress would in itself cause a discharge in the outer regions; but we cannot deny that under the existing conditions these regions do not insulate, and Lord Kelvin's argument still holds good.

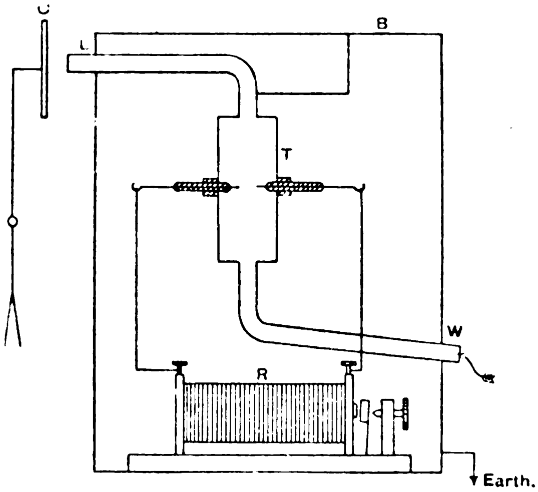

Fig. 2.

But the question of the ending of the lines of force—in other words, the location of the positive charge corresponding to the negative electrification of the surface of the earth—can only be solved by balloon or kite experiment, and we may shortly mention the more important results which have been so far obtained.

Observations made up to heights of about 1,000ft. seem to indicate a strengthening of the electric field, *i.e.*, the fall of potential per metre is greater at a height of, say, 200 metres than on the surface of the earth. We may mention especially the observations of Dr. Leonhard Weber (*Elektrotechnische Zeitschrift*, April, 1888), which bring out this point clearly. In one case the fall of potential at a height of 350 metres was found to be six times that at the earth's level. This increase is in itself not surprising, if we remember that every particle of dust raised from the ground must itself be negatively electrified, and possibly the observed increase in the electric field is sufficiently accounted for by the presence of electrified dust.

* "Veröffentl. des Kgl. Preuss. Stat. Bureaus," 1886, p. 177, quoted by Bebber, Meteorologie, p. 245.

Observations made at greater heights in balloons, on the other hand, seem clearly to indicate that this increase soon ceases, and that a diminution takes place at moderate heights already. Thus the observations of Dr. O. Baschin (*Meteorologische Zeitschrift*, September, 1894) gave for the fall of potential in volts per metre the numbers 49, 28, 13 at heights of 760, 2,400, 2,800 metres respectively, and at a height of 3,000 metres no measurable fall at all could be obtained. These observations were made in clear weather. The balloon afterwards passed over a layer of clouds, and strong electric effects were noticed. Similar observations had been previously made by others (Andrée, Le Cadet, and Bornstein), and though the subject is by no means exhausted, we may take it as provisionally established that the lines of force of the normal electric field of the earth end within the first 10,000ft. or 15,000ft. This result is of great importance, for it shows that there must in fine weather be a layer of positively electrified air permanently above us. Currents of air in this layer must affect the field as we observe it, and possibly the daily changes may be due to changes in the currents of air at a moderate height. A fact discovered by Exner is of importance in connection with this subject. Observing at three different places (in a field close to Vienna; in St. Gilgen, on the Wolfgangsee; and in Venice, on the hills), he found that whenever there was a strong south wind, with a clear sky, the normal fall of potential was always increased, and sometimes considerably.*

The daily changes show, with few exceptions, a remarkable uniformity at different places. There are in general two maxima—one at 8 or 9 o'clock in the morning, and one in the evening. The evening maximum is the most marked, while at some places, and especially near towns, the morning maximum disappears. The same general features of the daily variation have been found to hold at a number of European stations, at Cape Horn, Melbourne, and in the Northern Arctic regions. If the variation is separated into two—one having a period of 24 hours, and the other of 12 hours—the latter is found to agree in phase at widely different places on the earth's surface, while the former is found to vary to a much greater extent, and hence to be probably more affected by local circumstances. The remarkable researches of Hann have given a similar result for the diurnal variations of the barometer, and we may reasonably conclude that the semidiurnal variation of atmospheric electricity is connected with that same circulation in the upper regions of the atmosphere which shows itself in the corresponding changes of pressure.

In addition to the more regular periodic changes, the electric stress observed in fine weather shows marked differences on different days and at different seasons. With respect to these the researches of Prof. Franz Exner† have led to the important result that there is a close connection, direct or indirect, between the amount of aqueous vapour present in the atmosphere and the fall of potential observed at the surface of the earth. If p_0 be the pressure of aqueous vapour present in centimetres, Exner deduces the equation for the fall of potential P

$$P = \frac{A}{1 + k\,p_0},$$

where $A = 1300$, $k = 13{\cdot}1$.

The formula agrees very well with observations in which the vapour pressure varied between 0·23 and 0·95, and it is especially to be remarked that it is the amount of vapour and not the humidity which determines the fall of potential. Observations made by Mr. E. Drory during a journey round the world fit in very well with Exner's formula, and observations made at such widely-different places as Suez, Albany, Sydney, Colombo and Penang showed a fall of potential practically identical with that calculated from the above formula, though the same constants were taken and the vapour pressure varied between 0·8cm. and 2·2cm.

Messrs. Julius Elster and Hans Geitel‡ have followed up this research. Their investigations have shown a satisfactory agreement with Exner's formula, if the mean values of a number of observations, in which the vapour pressure is approximately the same, is considered. But individual numbers differ very widely from the mean, so that the formula cannot be used to predict the normal fall of potential on any particular day. There is, perhaps, nothing surprising in the great divergence of such individual results if it is considered that we only observe the moisture near the surface of the earth, but know nothing of the total amount of water in the column of air over the district in which the observations are carried out. The same authors have shown that an equally good agreement can be obtained if, instead of the amount of aqueous vapour, we take the intensity of active radiation as the determining circumstance. The light might be supposed to act on the general surface of the earth, as it does according to Hallwachs' observations on a metallic body, dissipating a regular charge. There are some difficulties in the way of this explanation, the most serious being the absence of experimental evidence that sunlight actually does act in the manner indicated on any substance forming part of the earth's surface. It is impossible at the present time to enter more fully into this subject, but attention must be drawn to the very important indirect result, that there seems to be a connection between ultra-violet radiation and the amount of aqueous vapour present in the air.

The phenomena of atmospheric electricity have been studied at the mountain observatory established on the "Sonnblick," in Salzburg, at a height of 3,100 metres.

The important result has been established that the fall of potential is singularly constant. The great differences observed at low levels between the electric field in summer and winter, or on dry and wet days, seems to be completely absent, and these facts tend to support the conclusion derived from balloon observation, that the positive ends of the lines of force are situated at a height of something like 10,000ft.

(*To be concluded.*)

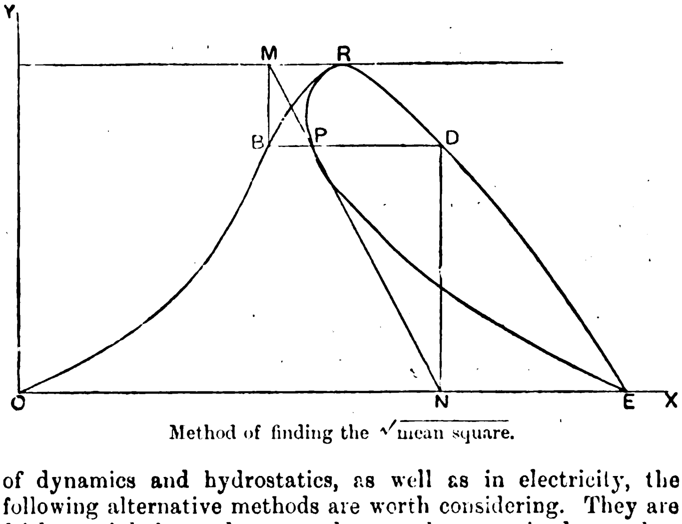
GRAPHICAL METHODS OF FINDING MEAN-SQUARE VALUES.

BY ALEXANDER RUSSELL.

Dr. Fleming, in *The Electrician* for May 10th, has given a valuable graphical method of finding the mean-square of a series of values of a varying quantity. As the problem is an important one, occurring, as it does, in many applications



Method of finding the $\sqrt{\text{mean square}}$.

of dynamics and hydrostatics, as well as in electricity, the following alternative methods are worth considering. They are fairly straightforward ones, and once the curve is drawn they involve very few measurements of length, and hence this source of error is reduced to a minimum. The latter of the two methods given is an instructive exercise for junior students, and when the precautions described are taken it gives accurate results.

Method I.—Let O R E be the curve (*see* figure), the ordinates of which give the values of the varying quantity. Draw a series of lines parallel to O X, like B D. If the curve be drawn on sectional paper, this part of the construction is unnecessary, as the ruled lines will do. Draw B M and D N perpendicular

to the tangent to the curve at its highest point R and to O X respectively. If we are using sectional paper, M and N can be marked without actually drawing the perpendiculars. Now mark the point P where M N cuts B D. Similarly, find other points, like P in the lines parallel to B D. Draw R P E, the curve passing through all these points. Measure h, the maximum height of the curve; l, the length of the base O E; and A^1, the area of the curve R P E D.

Then $$Y^2 = \text{the mean value of } y^2 = 2\frac{h}{l}A^1 \quad . \quad . \quad (1)$$

The practical rule is, therefore: Construct the curve locus R P E, find the area R P E D by the planimeter or otherwise, measure the height and breadth of the curve, and then use the formula (1) to get the $\sqrt{\text{mean-square}}$ of the height of the curve.

A short proof of (1) is as follows:—

The volume of the solid generated by the revolution of the the curve O R E round $OX = \pi\int_0^l y^2\,dx$.

It also $$= \int_0^h 2\pi y \,.\, BD\,dy;$$

$$\therefore \quad \int_0^l y^2\,dx = 2\int_0^h y \,.\, BD\,dy.$$

But from similar triangles
$$y \,.\, BD = h \,.\, PD;$$

$$\therefore \quad \int_0^l y^2\,dx = 2h\int_0^h PD\,dy$$
$$= 2hA^1;$$

$$\therefore \quad Y^2 = \frac{2h}{l}A^1.$$

In the second method we make use of the following theorem:—If y_m = the mean height of the curve, and y = the height of the centre of gravity of the area bounded by the curve,

then $$y_m = \frac{A}{l}$$

and $$2y = \frac{\int_0^l y^2\,dx}{A}$$ where A is the area of the curve.

$$\therefore \quad 2y \,.\, y_m = \frac{\int_0^l y^2\,dx}{l} = Y^2. \quad . \quad . \quad . \quad . \quad . \quad (2)$$

This formula enables us to write down at once the $\sqrt{\text{mean-square}}$ when we know the area and the centre of gravity of the area bounded by any curve. Applying this rule to finding the $\sqrt{\text{mean-square}}$ of geometrical figures like triangles, trapeziums, arcs of circles, &c., is an instructive exercise and shows to a certain extent how the mean height and the $\sqrt{\text{mean-square}}$ value of the height of a curve vary with its shape. For example, in a triangle

$$2y = \frac{2}{3}h \text{ and } y_m = \frac{1}{2}h \;\therefore\; Y = \frac{h}{\sqrt{3}}.$$

It is to be noted that y_m, Y and $2y$ are in geometrical progression, and are, therefore, arranged in order of magnitude; many theorems follow from this, the interest of which, however, is more mathematical than electrical, such as finding families of curves which have the same Y's, &c.

Method II.—Whatever the shape of the curve is, we can always find its area A, and the position of the centre of gravity of its area, by well-known experimental methods. Measure the height of the centre of gravity above O X (y) and the breadth of the curve (l). Find $y_m \left(= \frac{A}{l}\right)$; then Y can be calculated from the formula $\sqrt{2y \,.\, y_m}$.

It is particularly easy to find the position of the centre of gravity of a plane area by experiment. First cut out the curve in stiff paper. Hang it up by means of a fine needle, round which the curve swings freely. Fasten a key or other heavy object to the needle by means of a silk thread forming a plumb line, and make a mark where this line cuts the lower edge of the paper. Displace the curve and see that when it comes again to rest the silk thread is over the mark. Then rule a fine line through the point of suspension and this mark.

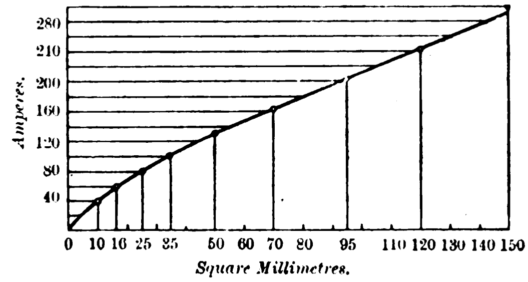
In a similar way rule another vertical line through another point of suspension. Where these lines intersect gives the centre of gravity of the plane area.

GERMAN INSTALLATION RULES.

A Committee of the Verband Deutscher Elektrotechniker has recently drawn up some rules relating to electrical installations, which will be submitted to the Verband for adoption at their annual meeting, which is to be held at Munich at the beginning of July. These rules, from which we abstract the most important points, apply to installations in buildings and private houses, in which the potentials from 25 to 250 volts, either continuous or alternating, are used.

The temperature of the wire of regulating resistances must not exceed 200°C., and the apparatus must be so erected that combustible objects close by are not heated above 60°C. For conductors it is laid down that copper should be generally used, the conductivity to be such that a 55-metre length of a wire of one square millimetre section has at 15°C. a resistance of 1 ohm. This works out at only about 93 per cent. conductivity according to Matthiessen's standard.

The highest admissible current for copper wires and cables is to be deduced from the annexed curve. An examination of this curve will show that, compared with English practice, a very high current density is permitted.



The smallest permissible cross-section for conductors is one square millimetre (about No. 18 S.W.G.); for fittings 0·5mm. (about No. 21) for each glow lamp. In places where the use of copper is not suitable, iron wires of at least four times the section of copper are allowed. The smallest admissible section for flexibles is one square millimetre.

The construction of fuses must be such that by fusing no permanent arc can be created. In lead fuses the contact must not be made by the lead direct, but contact-pieces of copper or other suitable material must be sweated to the ends of the lead wires or strips. Fusible screw-plugs of lead may only be used up to 25 amperes. Not more than 12 glow lamps or a current of 10 amperes may be protected by a single fuse.

The insulation resistance of two conductors against each other, and also of each conductor and earth, must give at least the value expressed in the following formula:—

$$R = 10{,}000 + \frac{2{,}000{,}000}{n} \text{ ohm},$$

where n is the total number of glow lamps (presumably 50-watt) connected, one arc being reckoned an equivalent of 10 glow lamps, the same ratio applying to every motor or other current-consuming apparatus. In making insulation tests to earth with continuous current, the negative pole of the generator should if possible be connected to the conductor which is to be tested. The readings must only be taken after one minute's electrification. All insulation tests must be made with the working pressure. In multi-wire systems the pressure at the lamp is to be taken as the working pressure. In all the insulation tests all glow lamps, arc lamps, motors and other apparatus must be disconnected, but all fittings, fuses and switches should be in the circuit.

ON THE RECENT DEVELOPMENT OF THE SINGLE-ACTING HIGH-SPEED ENGINE FOR CENTRAL STATION WORK.*

BY MARK ROBINSON.

(*Continued from page 96.*)

20. *Brake Efficiency.*—Having fully dealt with the three special points of advantage peculiar to single-acting engines, enumerated in paragraph 11, it will be of interest to investigate the effect of the single-acting principle upon brake efficiency. Generally, a single-acting engine has higher brake efficiency, when fully loaded, than a double-acting engine. The perfect lubrication of all brasses and bearings in the spash chamber of a single-acting engine naturally reduces that part of the friction to a very small figure, and the total absence of back-lash, or "lost motion," is believed to tell as strongly in the same direction. On the other hand, singly-acting engines, or at least the Willans engines, though they have no stuffing boxes, have unusually numerous piston and other rings, mainly owing to the practice of putting a complete tandem engine over each crank—or three cylinders over each crank, if triple expansion. Nine complete cylinders,† as fitted in three-crank triple-expansion engines, with their valves and glands, imply a large number of rings, and even in a two-crank compound engine there are a good many. The special design of the rings, which has been fully described in paragraph 12, coupled with accuracy in manufacture, bring the total friction, however, to a reasonably small amount. After some months' running, it is not uncommon to find the brake efficiency of compound engines as high as 92 per cent. ; but on trial at the works, when the rings are new and not yet brought up to a good face, it is rare to get more than 90 per cent., and 89 per cent. would not be thought unsatisfactory. In a triple-expansion engine 87 or 88 per cent. is a good result when new. Though experiments are sadly wanting, it is believed that these figures are much about the same as those for good double-acting engines, in which there is less ring friction but more bearing friction.

21. Mr. Willans' diagram of total water consumption, shown in the discussion upon Mr. Crompton's Paper upon the "Cost of Electrical Energy,"‡ has familiarised everyone with the rather puzzling fact, that in almost all trials at Thames Ditton, with good dynamos, the lines representing total water per electrical horse-power and per indicated horse-power remain nearly parallel for all loads ; in other words, the combined engine and dynamo losses, and *à fortiori* the engine losses alone, are as great at light as at heavy loads. Makers of some double-acting engines are believed to have obtained results differing from this, and showing a considerably reduced engine friction at light loads. Probably both are right. In both types the ring friction is constant. In the single-acting engine the bearing friction is also practically constant, because its maximum is so small that variation in it is unimportant. In the double-acting engine the bearing friction§ at full load is relatively great, and as it falls off at light load, it considerably reduces the total friction. If the single-acting engine beats the other handsomely at full load (as it often does), the effect may only be to bring them together at light load ; but where the double-acting engine is exceptionally free from friction, and makes a more even fight with the single-acting engine at full load, it may have a distinctly higher efficiency at light load.

22. The value of improved efficiency at light loads is not large, for the unwisdom of running an engine at light load, for any permanent use, is too great to be redeemed by any probable saving in engine friction. If light loads have to be faced, there should be a smaller engine to undertake them, small enough to make a full load of them, or nearly so.

23. The possible higher efficiency of double-acting engines at light loads is well illustrated in a Paper read by Mr. Alexander Siemens before the North of England Institute of Mining and Mechanical Engineers, in December last. It describes fully a series of trials in the central power-station belonging to his works at Woolwich, between a Willans engine (3-crank) of 300 I.H.P. and a Belliss double-acting engine (2-crank) of the same power, and running at the same speed, 350 revolutions per minute. The dynamos were apparently identical, and all the conditions appear to have been as favourable to a fair test as they can ever be in a commercial engine room. There are anomalies in the very interesting figures given, but there is no reason to mistrust their general tendency. At 270 I.H.P., the highest power used, the combined efficiency of the Siemens-Willans plant was 86 per cent., against 85·1 per cent. in the Siemens-Belliss, but at light loads the advantage of the latter was considerable, as appears below :—

——	Electrical H.P.	Indicated H.P.	H.P. lost in engine and dynamo combined.
Willans set	231·2	268·9	37·7
Belliss „	230·4	271·6	41·2
Willans set	114·6	149·2	34·6
Belliss „	120·3	144·7	24·4
Willans set	60·9	95·7	34·8
Belliss „	60·5	79·4	18·9

There is much in these figures which is with difficulty reconciled with any probable assumption as to the respective engine and dynamo losses ; but there is no doubt that in the double-acting (Belliss) engine the friction became very small at light loads. As it had but two cylinders and ran at high speed, there could be but little ring friction at any load, and it looks as though, *at light loads*, the bearing friction almost disappeared ; probably the crank-pins and shaft "floated" in their brasses, permanently separated from them by the oil which was forced in under pressure. It is, however, instructive to notice that with increasing load, and notwithstanding its great advantage in regard to ring friction (it probably had little more than one-third as much ring friction as the other engine), the total friction of the double-acting engine rapidly overtook that of its rival, and it is evident that had trial been made at the much higher mean pressures frequently used in non-condensing stations, the advantage of the single-acting engine would have been very marked indeed. It seems possible that, although the exceedingly elegant system of lubrication adopted in this double-acting engine is effective when the pressure per square inch on the brasses is light, yet the alternating pressures of the parts begin to produce their natural effect at heavier loads. In the single-acting engine security from wear and knock is obtained by ensuring that the revolving journal shall remain always in steady contact with *the same* brass : in the remarkable double-acting engine described, an even more perfect result is perhaps obtained *at light loads* (which, however, are not of the highest importance) by providing that the revolving journal shall touch *neither* brass ; but it remains to be seen whether in continuous running at heavy loads, the brasses will not relapse more or less into the condition of those of an ordinary double-acting engine. It is at least plain from the Woolwich figures that even at 270 I.H.P. the bearing friction (as distinguished from ring friction) of the double-acting engine is enormously greater than that of the single-acting engine, and the law of its increase might well repay investigation. Provisionally, it is difficult to resist the conclusion that bearing *friction* —*i.e.*, the actual rubbing of the journal upon the brass—is of small importance in engines in which the lubrication is very perfect, as in the Willans engine through its oil bath, or in the Belliss engine through the forcing-in of oil under pressure,* and that, in double-acting engines, at heavy loads, the most important element of friction-loss—or, it may be safer to say, of power-loss—is to be traced to the knock of the journal as it changes over from one brass to the other—a source of loss which the single-acting (constant-thrust) engine avoids altogether. Whatever be the ultimate verdict, no one can withhold admiration from the ingenuity and indeed beauty of the device by which it is sought to overcome so great a difficulty, and it is most satisfactory that in such an interesting and important trial, the double-acting principle has been, and continues to be, represented by so perfect an example.

24. Passing to the results of experience with single-acting engines in the last few years, it may be well to deal separately with—

(*a*) Steam Consumption. (*c*) Lubrication.
(*b*) Durability. (*d*) Vibration.

25. *Steam Consumption* (*a*).—The consumption of the best-known type of single-acting engine, under all loads, is known not only from the almost historic series of tests conducted by Mr. Willans, but from numerous other trials carried out at Thames Ditton.

---

* Paper read before the Institution of Electrical Engineers

† *Twelve* complete cylinders, has been unkindly said, reckoning the guide or cushion cylinders. But the reproach is not quite just, since the guide cylinders, with their ring-less pistons, merely represent the guides and cross-heads of other engines, and are quite as simple.

‡ *Proceedings* of the Institution of Civil Engineers, Vol. CVI., 1890-1.

§ In "bearing friction" is here included that which is assumed to be due to back-lash, *i.e.*, to the incipient "knock" necessarily present where there is alternation of stress. It is to be remarked that the heat generated by knock upon brasses is wholly lost ; but heat generated by piston-ring friction is partly utilised in heating the cylinder walls and pistons, and so reducing condensation. In the single-acting engine, therefore, a greater proportion of the friction loss is returned in reduced consumption of steam, than in a double-acting engine having the same total friction.

* If the mere rubbing of the journal and brass together, at heavy loads, were seriously important in a thoroughly lubricated engine, the Willans engine would show increasing friction at heavy loads. It does not do so, and even the moderate increase (in engine and dynamo together) shown in the figures extracted from Mr. Siemens' Paper, is exceptional. The increase in the Belliss engine, therefore, can hardly be due to this cause, and other reasons must be found for the increase which undoubtedly occurred.

Digitized by Google

It is, however, a frequent objection that the small consumption of steam per kilowatt upon test, bears little relation to the actual consumpton of coal per kilowatt sold : and doubt is often expressed whether the engine consumption does not increase with use and wear, or whether test figures are not vitiated later by variation in load. It is satisfactory to be able to answer this question. At the stations of the Westminster Company, Dr. Kennedy, F.R.S., has for a long time had accurate records kept of the quantity of water supplied (by meter), as well as of the load upon each engine separately. The "Thames Ditton" consumption for every engine at all loads is, of course, known, and has been compared with the actual consumption, and after allowance for steam known to be condensed in pipes and used in pumps, &c. (mostly ascertained by experiment), the result is *an almost exact balance.* Probably there really are unrecorded losses for which a margin would have to be provided, if it were not that the engines work at a little less than the calculated consumption, since the latter is, of course, based upon the trials of the same engines at the makers' works, when new and stiff. Some of the engines at the stations had been at work for over five years, and few for less than two years, so all had had time to bring the rings and other wearing surfaces into the best condition for economy.

26. At the meeting of the Institution of Mechanical Engineers, on April 24, 1895, the above facts were well shown in a diagram exhibited by Mr. G. M. Clark. Two cases were taken, from the same station : one for a heavy winter load, covering 24 hours ; the other for a week's load in summer. The leading particulars were :—

—	Winter load (24 hours).		Summer load (one week).	
Output in kilowatt-hours........................	3,350		9,000	
Measured total water consumption per kilowatt-hour .... lbs.	...	46	...	48
Measured steam consumption of engines at Ditton trials (full load, non-condensing), per kilowatt-hour .... lbs.	32·5		32·5	
Calculated addition to steam consumption (non-condensing) on account of low load factor .... lbs.	8·0		9·5	
Total calculated engine consumption per kilowatt-hour .... lbs.	40·5		42·0	
Measured consumption of steam in pumps per kilowatt-hour .... lbs.	1·5		1·5	
	42·0		43·5	
Balance, attributable to condensation in pipes, leaks, &c., ascertained by previous trials to vary from 7 per cent. to 11 per cent. of total consumption .... lbs.	4·0	46	4·5	48

These figures may be commended to those gentlemen of the technical Press who tell us that theory never helps anyone ; that no engine builder knows within pounds what weight of steam his engine is likely to use in practice ; and who apparently reckon no man practical if he knows the reason for what he does or is able to forsee the result.

27. It is important to inquire whether the economy of the single-acting engine may be expected to make any notable advance beyond the results hitherto obtained. The answer is Yes, but here (speaking of the Willans engine only) it is necessary to distinguish between actual engines as fitted in the majority of stations, and the new type only recently made. Owing to various circumstances, the demand for the central-valve engine came at first chiefly from users who desired to work without condensation, and its fame was first established by Mr. Willans' Paper upon Non-condensing Trials, in which he showed figures not before supposed to be possible for non-condensing engines (such as a consumption of 18·45lb. of steam per indicated horse-power with 170lb. pressure, triple-expansion ; and 19·45lb. with 150lb., compound). But Mr. Willans' Paper, and his practice at that time, did more than this—they pricked the bubble of over-expansion. Here was a little non-condensing engine which, with five or six expansions, used scarcely more steam per indicated horse-power, and obviously less per brake horse-power, than many large (not to say overgrown) condensing engines which expanded their steam twenty-fold or even thirty-fold. But the ease of the triumph tended to mislead, and the same ratio of expansion, without the moderate increase which was really desirable, was provisionally attempted in condensing work. A few months before his lamented death, Mr. Willans carried out a complete series of condensing trials, which proved that, while nothing could justify the excessive expansion formerly allowed by some makers, the Willans engine, as then made, erred, though less seriously, in the other direction. A new series of engines has since been designed in which the necessary greater expansion is provided for, the ratio of the cylinders being altered at the same time ; and in which a number of minor improvements, tending to the suppression of petty losses, considerable in the aggregate (but much less important in a non-condensing than in a condensing engine), have been introduced. From these engines, which have but just commenced to find their way into station work, great economy may be expected. The earliest was a triple-expansion mill engine indicating up to about 500 H.P., driving the flax mill of Messrs. Gunning and Campbell (Limited), at Belfast, at 300 revolutions per minute, and in some very complete trials carried out last year by their consulting engineer, Mr. A. Basil Wilson, M.Inst.M.E., after the engine had been at work for about six months, a consumption of 12·48lb. of steam per indicated horse-power was recorded. This places the single-acting engine, to say the least, in the very foremost rank of economical motors. Evidently electrical engineers need not fear that they must abandon economy if they do not "stick to the builders of mill engines and marine engines." In fact, it seems not impossible that, while advocates of the "mill engine" are pleading for central-station work, they may find themselves the victims of a flank movement, and learn too late that their special patrons, the mill engineers and owners, are becoming as open minded as the electricians, even to using "electric light engines" for driving their mills.

28. It may be remembered that in Mr. Willans' Paper on Non-condensing Trials, figures were given for one condensing trial at 170lb. pressure, carried out with the same triple-expansion engine as had been used for the non-condensing trials : the consumption was 15·1lb. per indicated horse-power per hour. With the old engine that result has not been much improved upon, so it may be reckoned that the new series are about 15 per cent. better in steam economy than the old, *when condensing.* For non-condensing work, and for condensing work in special cases, the old series engines are still the most suitable, while from the smaller cylinder capacity they are less costly to make. The engine at Messrs. Siemens' works at Woolwich, the trial of which against a Belliss engine has been before referred to, was of the old pattern, compound, but fitted with the "transfer" arrangement : in other respects it was of the proportions now recognised as suitable for non-condensing only. The steam consumption at full load is given by Mr. Siemens, in his Paper before quoted, as 19·5lb. per indicated horse-power, against 22·4lb. in the double-acting engine. It is understood that these figures of steam consumption are based upon the total water actually supplied to the boilers, with a deduction only for steam used in pumps ; they presumably include pipe condensation and leakages of all kinds, and it is probably from some such causes, rarely absent from a commercial engine room, that the water used comes out some 2lb. per indicated horse-power per hour above that due to the proper steam consumption of the old-type Willans engine at the load and pressure stated. (The vacuum is not given.) Of course, the Belliss engine was similarly affected.

29. Reference has been made, in paragraph 20, to the numerous cylinders of the Willans engine, due to the practice of erecting a complete engine over each crank. By adding to the number of pistons and valves the ring friction is, of course, increased, and it is equally certain that condensation is increased, and economy affected unfavourably, owing to the larger aggregate surfaces of the two or three small cylinders which take the place of what might otherwise be a single large one. On the whole, however, the advantages appear to outweigh the drawbacks. The first and most obvious is even turning moment. Whatever the change in load, in pressure, or in cut-off, it is at least certain that the cranks will be driven equally, and this is an advantage not to be lightly surrendered for only a small gain in economy. But the same tandem arrangement of cylinders is also the condition of the complete application of the Cornish cycle to all the cylinders except the low-pressure one : the perfect separation between the temperature ranges of the successive cylinders is impaired if their strokes do not succeed each other at intervals of exactly a revolution—as they now do in the tandem pattern ; even economically, therefore, there is something to be said in favour of the many small cylinders. Turning to other considerations, it may be thought at first that the large number of small cylinders and multiplication of parts must lead to increased weight and cost, as well as to difficulty in dismantling and overhauling. As to weight, it is almost certain that it is not increased. Cylinders weigh roughly in proportion to volume, but the weight of a piston tends to increase faster than the area ; three pistons, each of one square foot area, will weigh less than one of three square feet area. To cylinder covers the same consideration applies. Piston-rods, connecting-rods, and crankshaft should be unaltered. There may be some saving in machine work, but small pieces are after all easier to machine than large ones, and pieces which are made in batches of say, 36, are more economically manufactured than

Digitized by Google

larger pieces made in batches of 12 only. Then the identity of the several lines of parts, and their interchangeableness, are often helps to the user (especially in case of repairs), while the lightness of the individual pieces and the regular and simple routine in removing them make dismantling easy. A Willans cotton mill engine of 650 I.H.P. pulled up one day after the dinner hour with brasses cut to pieces and crankshaft badly scored. (Of the cause, it need only be said that emery powder was found in the bearings and in the crank-chamber.) *Next morning*, after breakfast, it started again with new brasses, and crankshaft in good order. By good luck another engine of the same size was being erected in the same town, and its brasses were at once appropriated for the disabled engine, and every necessary repair thoroughly carried out during the night. It is true that in this case the cylinders did not require to be lifted, but there have been as rapid repairs to cylinders, pistons, &c., where internal damage has been done by water. Some years ago, three 3-crank triple-expansion engines of 300 I.H.P., to save the reproach that they had nine cylinders each, were designed with only six cylinders, viz., one high-pressure, two intermediate, and three low-pressure. It is remarkable that not only have all later engines of the same type been fitted with the orthodox nine cylinders, but the original engines in question are now being altered to the standard pattern. With larger sizes may, possibly, come different views, but as regards the present standard patterns 700 I.H.P. or 800 I.H.P., experience gives little support to objections against the number of cylinders.

30. A discussion upon the economy of the single-acting engine should include running expenses other than steam, but this would greatly lengthen the Paper. Moreover, it is only users who can pronounce upon this question finally and with authority. That single-acting engines of the closed type are very economical in oil is generally allowed, and economy in attendance is also conceded. An engine which oils itself cannot want much looking after. Repairs are the only point which really admits of dispute, and these are dealt with under "durability" in the succeeding paragraphs.

31. *Durability*.—The idea that because a machine makes many revolutions a minute it must wear out more rapidly than a slow-running machine, seems to have the force of an axiom for some minds. Yet there is nothing axiomatic, nor even, to the instructed, probable about it. In the first place, high speed is a very winnowing fan in the matter of workmanship. It is surprising what a slow-speed engine can endure, for a season, in the way of bad workmanship; but not so the high-speed engine. If it will run at all, there is probably no reason it should stop, so far as workmanship affects the question. In the next place, the piston speed is usually much lower than in slow-running engines, owing to the short stroke; about 525ft. a minute is the highest piston speed in any single-acting electric light engine. The wear of piston rings and cylinders is bound, other things being equal, to be proportional to the piston speed, and this applies also to valves and glands. In one important point, however, other things are not equal, but are largely in favour of the single-acting engine. The system of packing rings described in paragraph 12, which cannot be used in double-acting engines without much complication, has decisive effect upon cylinder wear, and even if one went back to the records of the old vertical beam engines, which used steam at 30lb. per square inch, and have been described as "revolving occasionally," it may be doubted whether such evidence of good wear could be found as is now to be quoted in favour of the fastest running engines.

32. The makers of the Willans engines have for some years past lost no opportunity of obtaining and recording exact measurements of wear where they have been called in to carry out overhauls or examinations. The results are systematically recorded, and they show, speaking generally, an absence of wear beyond all claims made or expectations formed by those interested in the engine. On March 9, 1895, a G.G., or 80-I.H.P. compound non-condensing engine, No. 906, used for lighting one of the largest hotels in London, and stated to have run (at about 400 revolutions per minute) for 14 hours per day, including Sundays, was taken down for overhaul—never having been so much as taken down for examination since its erection in April, 1890—that is, *five years* previously. The report states that "all the parts were carefully measured, and the high-pressure and low-pressure trunks showed no perceptible wear, and were replaced the same as they were taken out. On measuring the high-pressure cylinders we found they were two-thousandths of an inch larger than our standard size, and the low-pressure cylinders were the same; still they were quite round. All piston rings and gland rings were replaced without any repairs whatever. The whole of the repairs to this engine, including taking down and re-erecting, were executed in 24 hours."

33. It will be justly said that if such a report reflects great credit upon the engine, it reflects no less credit upon the engineer who has charge of it. The constant and heavy work in this case is no real disadvantage: the chances of corrosion during stops of a few days are much more injurious. In a lighting station where work is more intermittent, and where during the summer engines are liable to be laid off for comparatively long periods, the wear (or corrosion) is greater, and the following is an instance of what is looked upon as heavy wear under such circumstances. The engine is of H.H.-12 size, No. 999, being of an exceptional type—that is, having 12in. stroke instead of 8in. (as usual in H size), and running under 200 revolutions instead of at about 380; it was one of a pair ordered to a special specification, and from the point of view of objectors to high speed it should give good results. It was erected in March 1891, at one of the London electric lighting stations, and in February last it was taken down for an ordinary overhaul, and was re-erected. As the condition of the engine was manifestly good, and as it was non-standard, so that information about it had not the usual value, it was not measured, but hearing that a visitor to the station had measured the high-pressure cylinders while lying about, and had stated them to be much worn and considerably oval, the makers, though certain that the statement was a mistake, asked permission to take the engine down again, and made unusually full measurements, checked by more than one observer, in the presence of the chief engineer of the station. It appeared that in one cylinder, though the ovalling ranged only from two to seven 1,000ths, there was in one part wear (in four years) of 28 1,000ths, or nearly 1-35th part of an inch; the other cylinder showed about half this wear, and no ovalling.*

34. The third instance is of an engine working under really good conditions—that is, driving a cotton mill, and working therefore for long hours, and with scarcely any stops exceeding two days. This engine, No. 1,253, of 650 I.H.P., commenced work in April, 1892, and though the cylinders had been taken down before, they had not been closely examined or measured. At Easter, 1895, it was thought desirable to have the engine closely examined, and between the Thursday evening and the following Sunday afternoon it was completely dismantled, thoroughly examined and measured over, cleaned, re-erected, and started under steam. There was no repair of any kind to be done, and but for the accidental breakage of some studs during re-erection it would have been running a few hours earlier. The report upon wear was most satisfactory, but the facts are best given in the words of the inspector sent by Mr. Michael Longridge, who supervised the examination on the part of the owners of the mill. This gentleman wrote:—

"The cylinders were taken down and pistons and valves out; the cylinders are 17in., 28in., and 40in., with 1ft. 6in. stroke. Revolutions, 206; boiler pressure, 160lb. I examined and gauged all the six cylinders with a very fine gauge, one that can be set to one 10,000th part of an inch, and found high-pressure cylinder about one 1,000th part of an inch worn; intermediate-pressure cylinder one 3,500th part, and low-pressure one 7,000th part of an inch worn; indeed, the tool marks had not properly worn out. The surfaces as smooth as glass. The pistons and rings seem to be very good, and the rings of the piston-valves also appear to be very good, all bearing well round; the piston-rods or trunks also appear to have good surfaces; also internal surfaces, where the valves work, seem good, and the rings of the piston valves also appear very good, so that they scarcely appear to have been at any work. I must say that I never came across anything so accurately fitted together; even gauging the cylinders with the above-named fine gauge, I cannot say that I even found a slack place one way from another. Whether the engines are of good principle or not, the workmanship is good, which contributes to small wear and little friction. Crank-shaft necks and crank-pins seem very good, being very smooth." "Whether the engines are of good principle or not" is valuable; clearly the giver of this emphatic testimony is no devotee of the single-acting engine. All brasses and journals, eccentrics, &c., were stated by the overhauling staff to be in perfect condition.

35. When the single-acting engine has run n years it is always open to objectors to say (as they do) that no doubt it is good for n years, yet $n+1$ years will finish it. The argument admits of no refutation; that is, the present objectors may be right—for a year, though those of last year are refuted already. But reasonable men with such evidence as the foregoing before them will pay more heed to the counter-claim, which is, that the durability of the high-speed single-acting engine is not inferior to, but enormously exceeds, that of the best double-acting engines, unless the

* The statement which gave rise to the re-measurement was that one cylinder was fully an eighth of an inch oval, and that there was much tapering and wear generally. It was made beyond question in absolute good faith, probably from using inadequate or extemporised measuring appliances. The remarkable point was that the visitor was an engineer, and stated that he had been provoked to measure the cylinders by being told that no wear would be found in them; but that, "as an engineer himself, and accustomed to measure cylinders," he did not consider the wear, *as he supposed it to exist*, was excessive for the time the engine had been running.

Digitized by Google

latter revert to an archaic slowness of running, in which case their enormous size and cost will exclude them from practical consideration.

36. With many hundreds of single-acting engines at work, there are, of course, some cases of trouble. There have been broken crankshafts, though not in an unusually large proportion, if we exclude a succession of breakages in a single important station which attracted much attention. There were special reasons in that case which contributed to the result; but the plain and honest reason why the cranks broke (as with all other cranks which have broken since cranks began) is that they were simply not strong enough. The engines, which formerly had a 4-in. shaft, have for some years past had 5-in. shafts. The 4-in. shafts have broken, and the 5-in. have not, and are not likely to—apart from the effect of those occasional flaws against which no steel forging can be absolutely guaranteed.

37. Other cases of excessive wear, or of damage, when not referable to defective lubrication, may usually be traced to under-loading, *i.e.*, to running with so light a load that the pressure in the steam-chest becomes insufficient to hold down the lines of valves in constant thrust against the eccentrics. The single-acting engine has, of course, the defects of its qualities. Constant thrust is perfect so long as it lasts, but without it, the single-acting engine has no claim to admiration. For the pistons, and main moving parts generally, the question was settled once for all, so far as regards the Willans engine, by the well-known "air-buffers," which provide completely for cushioning, irrespective of change either of load or of back-pressure, the distribution of the steam by the valves being absolutely untrammelled by any consideration of cushioning. Unfortunately, the air-buffers do not cushion the valves, and it is as important that the latter should be held closely down upon the eccentrics as that the connecting-rods should not leave the crank-pins. The line of valves is fairly heavy, and owing to the eccentric being seated on the crank-pin, though the stroke of the valves relatively to the ports is moderate, yet the total stroke is nearly as long as that of the pistons. "Holding-down power" is intended to be given by the pressure of the steam in the steam chest upon the topmost valve, but if the pressure is too much throttled down, the "constant-thust" element is wanting, and the parts have to be checked upon the up-stroke, more or less, by the underside of the eccentric strap bearing against the sheave—a state of things which, at least in theory, is inadmissible in a constant-thrust engine. In practice, however, if there is good surface on the eccentric sheave, and a well-hardened pin at the small end of the eccentric rod, no serious results follow, provided the defect of pressure in the steam chest is only occasional, and is not too considerable. Under such circumstances, however, it is necessary to look now and then to the eccentric straps, and take up the wear if necessary, and to be warned in time if the engine begins to run noisily. The lesson of the wastefulness of running an engine at light load, if it can possibly be avoided, has now been so well learned, that in lighting stations at least (except, perhaps, in alternating stations where parallel running is not practised) there is little danger of the load, and consequently the steam-chest pressure, being allowed to fall low enough to jeopardise the "constant thrust" of the eccentric straps; but where such a probability exists it adds a reason for using variable expansion gear, which, of course, secures the maintenance of high pressure in the steam chest. In a throttling engine it is also easy to secure the required holding-down pressure on the valves by forming the little steam chest dome which tops each line of parts, as a cylinder, in which the uppermost of the line of valve pistons works. The top of each little cylinder is in communication with the steam pipe outside the throttle valve, and so gives a constant down pressure on the valves, irrespective of throttling. Of course, these fittings cost something, and they need special lubrication, so that it is only in very exceptional cases that it is worth while to fit them, and in such cases there are probably other sufficient reasons for using variable expansion gear instead. It is well to bear in mind, however, that in special cases, the durability of the valve motion may require to be secured by special precautions; it is not absolutely assured under all circumstances like that of the main working parts.

38. *Lubrication* (*c*).—Where the parts of an engine lie permanently in the lubricant, both when running and when standing, the quality of the oil is of more importance than where it is used in the old-fashioned way. Free acid in oil, which is more common than is usually supposed, leads to corrosion, and in some few cases has caused serious trouble; the quest for a perfect crank-chamber lubricant, which shall always be the same, is not quite ended yet. Cylinder lubrication has long ceased to trouble (if the user does not sacrifice everything to cheapness), but not so the other. Sometimes it would appear that acid is brought over in priming water from the boiler; in some cases it has been traced, with tolerable certainty, to special boiler compositions containing acids, which may find their way with priming water past the valves into the crank chamber. The tests for acid, however, are comparatively easy, and its presence is soon shown by the rusty red colour which the lubricant begins to assume, and, in worse cases, by the condition of the parts. Prevention also is usually easy, as by the use of small quantities of soda, or of soft soap, added daily to the crank-chamber in very minute quantities; if there is much of it, it "lathers" so successfully that it drives everything else out of the crank chamber. The "personal equation" enters much into this, as into other questions of engine management. There are many hundreds of closed engines running where trouble with lubrication has never been heard of; yet in a few, working apparently under identical conditions, everything is different. Where oil is of doubtful quality, temperature plays, or may play, an important part, and the advantage of keeping the crank chamber cool has for some years been recognised. In the Willans engine, cooling pipes are usually fitted in the crank chamber, through which, if the engine works non-condensing, it is well to run a small stream of water; about one-fourth of the quantity which is supplied to the engine as steam, per hour, is generally enough, but it is sometimes a convenient plan to run all the feed water through. In a non-condensing engine the crank chamber is hotter than in a condensing engine, because the main source of heating is conduction, by the walls of the crank chamber, from the "exhaust chamber" above. When the exhaust temperature is about 215deg., as in a non-condensing engine, the crank chamber, of course, grows hotter than where the exhaust is at condenser temperature. 170 F. is a perfectly safe temperature for the crank chamber; but the lower it is, the more one has, so to say, in hand, and it is such an advantage to have complete control over the temperature, that it is generally worth while to adopt the cooling pipes, even in condensing engines. The large ones are made, as shown in the section in the appendix, with a kind of water jacket to the crank chamber base. It is evident that the engines might be constructed with a more complete separation between the hot cylinders and exhaust chamber, and the cool crank chamber; there might, for instance, be an air space and columns between those parts. But, as is true of many other possible minor improvements, the gain from this arrangement might be bought too dearly; it is cheaper to take easy precautions against small and infrequent troubles, than to make the engine larger and more costly, even if theoretically more perfect.

39. *Vibration* (*d*).—The increase of town lighting stations gives great importance to the subject, but as it has recently been somewhat fully dealt with, as regards both engines for lighting stations and marine engines, in a Paper contributed by the author jointly with Capt. Sankey, R E., to the Institution of Naval Architects, it is not proposed to treat it at length on the present occasion; it will suffice now to say only enough to show in what direction improvement is most probable.

40. In a recent well-known case, several single-acting engines, supposed to be remarably free from vibration, have been removed from a London station, and replaced by steam turbines, as the only certain means of meeting the objections of persons living close by. What was the cause of the vibration, and how can it be avoided, without abandoning altogether the accepted reciprocating form of steam engine?

41. The station contained 10 engines of 200 I.H.P. each, and it is no exaggeration to say that a person standing on the great concrete block which formed the foundation for all the engines, could scarcely tell whether those near him were running or standing. Yet complaints from houses at some little distance (rather than from closer neighbours) were evidently well founded. The engines had two cranks each, 180deg. apart, as shown in Fig. 8, where there is an obvious couple, A B, which tends to set the engine rocking endways, and to give rise to vibration. But it was incredible that the huge block of concrete, measuring 88ft. by 24ft. by 7ft., could be tilted crossways by the couple between sets of pistons moving in lines only 2ft. 3in. apart. Besides, the effects produced, and the known nature of the subsoil, led to the belief that the block was not so much rocking as lifting up and down bodily, and acting like a pump upon the water-laden soil below (the complaints were most serious after periods of heavy rain). It would have been easy to balance the "couple" if that alone were the cause, by dividing one of the lines of pistons into two, each of half the weight, and using cranks as in Fig. 9, where B and B^1 are both at 180deg. from A, and the parts connected with them are collectively of the same weight as the one line connected with A. This plan is described in Lowrie's Patent No. 3,040, of 1885, and it has also attracted attention recently. The engine showed in Fig. 9 would have no tendency to rock endways, but it was soon seen that it would effect no improvement in the station referred to, for on closely examining the matter mathematically (in February, 1893), Capt. Sankey found that in the engines in question, and broadly speaking in all vertical engines, the tendency to rock endways, by reason of an unbalanced couple, was much less important than the tendency of the engine, as a whole, to move vertically up and down, through a cause depending upon the obliquity of the connecting rod. Previous calculations had usually been addressed

Digitized by Google

to balancing the couple, as a practical solution of the whole vibration question, and though it was known that the obliquity of the connecting rod had an effect on the result, it was believed to be disposed of by the statement that "the slight and immaterial errors due to the finite length of the connecting and eccentric rods need not be considered."*

42. The engines were central-valve engines of I.I. size, having lines of parts each weighing 420lb. They ran at about 350 revolutions per minute, and had a stroke of 9in.; the ratio of connecting-rod to crank was 4·77 to 1. The two points of maximum piston velocity are, of course, above half-stroke, hence the changes of piston velocity, and therefore the inertia forces, are greater in the upper half than in the lower half of the revolution. Without going into details, it appeared that when each line of parts was near the top-centre, it exerted an upward pressure upon the engine of 3·54 tons, but when near the bottom centre, it pressed downwards with only 2·31 tons. A B, in Fig. 8, therefore represents not only a couple but a force, for A and B alternately exceed each other by about 1¼ ton, twice per revolution. Twice per revolution there is a force of 1¼ ton trying to lift the engine; and twice per revolution this changes into a nearly equal force acting downwards. (The inertia curves establishing these results are

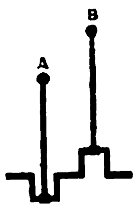

Fig 8.

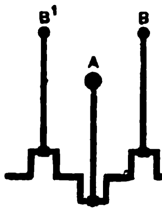

Fig. 9.

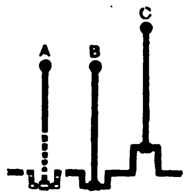

Fig. 10.

given with the Paper before mentioned.) A number of engines developing these unbalanced forces, and synchronising every few seconds, were probably well calculated to produce the results complained of. Needless to say the engine shown in Fig. 9, if comparable with that in Fig. 8, as regards revolutions, stroke, and total weight of moving parts, would give exactly similar results in respect of the unbalanced vertical inertia forces acting upon the engine as a whole.

43. At the same time Captain Sankey investigated the inertia forces in a three-crank (I.I.I.) engine, having the same revolutions, stroke, and weights of parts, but with three cranks at 120deg. instead of two at 180deg. Here the unbalanced vertical forces entirely disappeared, or rather, so nearly disappeared that they amounted to about two pounds only, as against 1¼ ton. It was concluded that if three-crank engines were substituted for the two-crank engines, the vibration difficulties would be ended, but the engineer of the lighting company naturally hesitated to adopt a remedy based chiefly upon calculation, for, although such three-crank engines were running elsewhere and with remarkable absence of vibration, there was nothing to show with absolute certainty

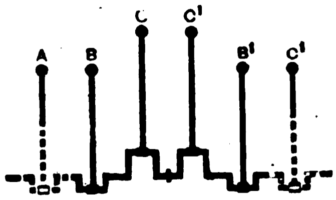

Fig 11.

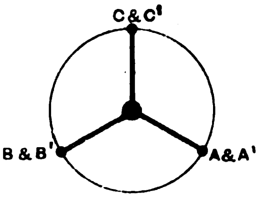

Fig. 12.

that the mathematical reason was the right one. He therefore shifted the engines to another station and put down steam turbines instead, feeling sure that they would at least secure the object of getting rid of vibration. The result was naturally to give an impulse to the use of three-crank instead of two-crank engines for lighting stations.

44. In 1894 the proprietors of the Heilmann system of electric traction were in search of vibrationless engines to mount upon two very powerful electrical locomotives they intended to build, and they applied to the author's company. The engines were to be of 1,400 H.P. each, and as they were to stand fore and aft on the engine framing, and as no weight could be allowed in the nature of "foundation," it was desired to eliminate the "couple" as well as the vertical inertia force. This, it is hoped, will be effected by the design shown in Figs. 11 and 12, proposed, in letters which crossed each other, both by the author and by Mons. Mazen, of the Compagnie des Chemins de Fer de l'Ouest, who is interested on the part of that company in the development of the Heilmann system. There are six cranks, virtually forming two groups, each

* Quoted from a patent specification.

representing a three-crank engine, with cranks 120deg. apart, and therefore, according to Captain Sankey's investigations, free from any tendency to vertical movement; if the two halves of the engine are thus free, the whole must be so. Each half of the engine, however, has a "couple," and tries to rock endways. It is designed to neutralise this effect by arranging the cranks as in Fig. 12, that is to say, by inverting the two groups relatively to each other, so that they shall rock systematically towards and away from each other. Both groups being mounted on one base, and enclosed in one crank-chamber, stiff enough to prevent deformation, it is clear that the engine as a whole will be subject to no rocking effect, and as it is also free from any unbalanced vertical forces due to the finite length of the connecting rods, it is believed that complete success will be attained. A dynamo is mounted at each end of the engine, so that each half of the crank shaft has only to transmit its own half of the power. It is evident that the two centre cranks, C and C', might be replaced by one, their two lines of parts being also replaced by one of the same total weight; the engine would then be five-crank, but it would lose certain advantages of interchangeableness of parts and of manufacturing facility.

45. Two such double engines are now under construction for a large London station, but inasmuch as longitudinal stiffness is amply provided by the concrete foundation, it is unnecessary to place the two groups of cranks in one crank chamber. Each set consists of two I.I.I.—S engines, each of 360 I.H.P., and each engine coupled to a dynamo. The engines are to stand end to end, the bases being bolted together, and the crank shafts connected by a detachable coupling (the governors are driven by gearing, so as not to interfere with the coupling). The cranks are arranged as in Fig. 12, and the coupling does not admit of their going together in any but the right position. Either engine may be used, for light loads, as a single unit up to 360 I.H.P., in a form little likely to give rise to vibration, while at full power, when under ordinary circumstances vibration might become more serious, it is hoped that by coupling together as explained, it will be entirely got rid of. The more conclusive experiment, however, will be in the Heilmann locomotives, where the engines, instead of being on solid foundations, will be, of course, suspended on springs.

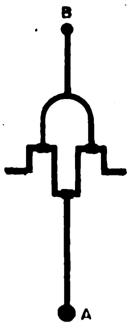

Fig. 13.

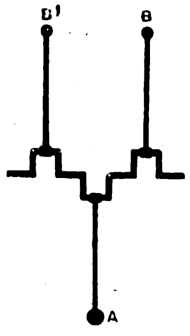

Fig. 14.

46. Perhaps the very simplest form of completely balanced engine is one which was used in the earliest Heilmann locomotive. It is shown in Fig. 13, which represents a compound engine. Fig. 14 shows a variation which might be used for a triple-expansion engine. Of course, in both cases the total weight of the moving parts must be the same on the two sides of the crank shaft, and the cranks must be 180deg. apart, and the connecting rods and cranks of equal lengths. Both figures are really a development of Fig. 9; but they provide, as Fig. 9 does not, for the varying inertia forces due to the finite connecting rods. The forces vary at the same times and in opposite directions, and so neutralise each other completely, instead of only partially, as in Fig. 9. This form of engine needs to be horizontal. If used as a vertical engine, one crank must be driven from below, which is practically impossible in a marine engine, and cannot be generally convenient in other situations. Since the cranks must be opposite, such an engine also cannot have the even turning moment of an ordinary three-throw engine, and for marine purposes it would require to be duplicated (*i.e.*, to have six cranks) for the sake of avoiding dead centres.

47. Numerous proposals have been made to balance engines by "bob-weights"—dummy pistons driven by eccentrics. The couples in an engine can be thus balanced: not the other forces, unless the bob-weights are placed below, as in Figs. 13 and 14, and are as heavy as the pistons. The subject is, however, far too complicated to receive more than superficial notice here.

48. In addition to the foregoing matters, it might be of interest to say something about the governing of central-station engines. This subject, however, needs a Paper, to say the least, to itself; moreover, experience with single-acting engines can teach no lesson substantially different from what may be learned from double-

Digitized by Google

acting engines, unless it be that the former, by reason of high speed and many impulses per minute, and the small amount of steam contained within the engine at any one time, are somewhat easier to govern. As regards steady running, in the sense of smallness of variation in speed during each revolution, the high-speed engine has, of course, enormous advantage. The engine before referred to as driving a flax mill in Belfast gives an almost perfectly straight line upon the recorder, although the instrument used could be set to feed the paper so quickly that the change of speed in each separate revolution was apparent; its effect was limited, however, to the width of a narrow line. In this engine, with three cranks, there were 900 impulses per minute, all exactly equal, and it was not wonderful that with a pulley flywheel weighing only 6 tons, and of 5ft. diameter, better results were attained than in slow-running engines with flywheels many times as heavy. The same remarkably steady drive has been observed in another engine of the same type (but with two cranks only) driving a cotton mill. This, of course, is not governing, but merely testimony to flywheel efficiency. It is a subject, nevertheless, of great importance, and one which perhaps was somewhat neglected in the earlier days of the high-speed engine, when flywheel power was certainly cut fine.

49. As the flywheels have been made more powerful, so have the governors. If central-station experience tells anything, it is that if you want prompt and sensitive governing and freedom from hunting, you must first provide a very powerful governor, and then give it next to nothing to do. The Willans governors are now, owing to the high speed of rotation, and the much heavier balls in use, enormously powerful in proportion to the work to be done, which consists only in moving the (piston) throttle-valve, and, in automatic expansion engines, the very small steam valve which controls the relay cylinder. The consequence is that a very restricted movement of the balls makes the desired change in minimum time, while leaving plenty of margin to deal with unaccustomed resistance, due to such causes as dirt or neglect. It is hardly possible that the most powerful shaft governor can have as much power, relatively to the calls upon it in shifting eccentrics, links, &c., as is possessed by the governor of any recent Willans engine.

50. There is no subject about which more confusion exists in engine-rooms than the relative parts played by the governor and by the flywheel. They are certainly closely allied, but very often when the governor is blamed, it is really the flywheel which is in fault, that is to say, with reference to the particular work the engine is called upon to do. On the other hand, many a governor owes its reputation to the flywheel, whose huge weight forbids the engine to take serious notice of a change of a load until the governor, possibly in itself neither a powerful one nor a good one, has had time to adapt itself to changed conditions. Of course, a heavy flywheel cannot affect the permanent change of speed due to a change of load, but it depends largely upon the flywheel whether the momentary variation shall be great or not.

51. The great question of throttling *versus* variable expansion has been fully dealt with by Capt. Sankey in a Paper read at the spring meeting this year of the Institution of Mechanical Engineers. It must suffice to say here that variable expansion is desirable for practical convenience, rather than for economy, in a great many cases, and for economy in some, but that in no ordinary case does the economy rise beyond a very moderate percentage, and that only through a small part of the range of variation of load. It is also established, upon the basis of Mr. Willans's experiments, that at very light loads (say quarter load, or even more) it is distinctly more economical to throttle the steam than to continue to make the cut-off earlier, and maintain the full pressure in the steam chest—since in the latter case, for only a small useful load, the full initial condensation is maintained, and the full loss by radiation. When the initial temperature in the first cylinder is reduced (as it is by throttling) both these sources of loss are diminished. Perhaps the most useful effect of automatic gear is that, by its aid, an engine can be occasionally overloaded without having to carry the same late cut-off at all times. Where the normal load is also the maximum load (as it should be in lighting stations, where the plant works in parallel) the engine is, of course, designed to give that load economically, *i.e.*, with cylinders of such size as to give the full load at a moderate mean pressure. In this case when light loads are carried—if they ever are carried: it would be better to avoid them—it is not of much importance whether the power is reduced by throttling or by altering the expansion. Now take such a case as that of electrical traction, where the average load is small, perhaps only half or two-thirds the maximum; it is evident that the cylinders, and the normal expansion, should be designed to suit the average load —but this cannot be done without the use of automatic expansion, because provision has to be made for the occasional overload. By automatic expansion it is possible to keep the cylinders of such an engine small, and suitable for the normal load, and yet readily take more power from it for short periods. The periods of overload are, of course, wasteful; but this is far less important than wastefulness during the much longer periods of average load.

52. The mode of varying the cut-off in the Willans engine is by a sleeve working upon the trunk or hollow piston rod, where it passes into the steam chest at the top (*see* description in Appendix). There are inclined ports in the trunk and in the sleeve, and by rotating the latter by means of gear outside (or sometimes inside) the steam chest, the cut-off is made early or late. The system adopted is one originally planned by the author, but which owes its practical form to improvements carried out by Capt. Sankey. A throttle valve is used, and on, say, a drop in load, reduces the pressure in the steam chest in the usual way. The rotating sleeves are controlled by a small steam cylinder, the piston of which is exposed to boiler pressure on one side, and to steam-chest pressure on the other. On the drop referred to taking place, the piston moves towards the steam chest, and the cut-off is altered, in the sense of being made earlier; means are provided to prevent too rapid movement of the cut-off gear in this direction; slowness or jerkiness of action is immaterial, because the throttle-valve has always control over the speed. As the cut-off changes the pressure in the steam chest gradually returns to what it was before, or nearly so. The return journey of the relay piston offers more difficulty, and, if effected only with the apparatus as yet described, it would require a considerable permanent difference of pressure between the steam chest and the boiler. Captain Sankey has made this unnecessary by providing that, when the engine speed *falls*, the spindle which moves the throttle-valve shall also move a small valve which both cuts off the boiler steam from the relay cylinder and allows the steam already in this cylinder to exhaust into the receiver, or some other place of lower pressure; as the relay piston moves it makes the cut-off later. The point of cut-off is at all times indicated externally by an index and pointer, the latter forming also a handle to enable the gear to be worked by hand, if preferred. The gear has the great advantage that by merely fixing a stop the range of variation of cut-off can be limited, so that on the one hand the engine may not be grossly overloaded, and on the other the expansion may not be carried too far for economy. In fact, the engine governs by varying the expansion down to a certain mean pressure (dependent, of course, upon boiler pressure and other circumstances), *and below that by throttling*, which is exactly the ideal arrangement for economy.

In conclusion, the author thinks it may fairly be claimed that the single-acting high-speed engine has justified the favour shown to it by electrical engineers, in regard both to that which it has already accomplished and to the prospect which it holds out of further successful development. Its success, as in all similar cases, has but fostered improvement in other engines, and it may be doubted whether central-station engines in this country, either of the slow-speed class or of the high-speed double-acting class, or even the deeply interesting steam turbine, would have attained to their present perfection had they lacked the spur applied by the progress of the Willans engine, and of others like it. For good or ill, the wide adoption of the single-acting high-speed engine marks a bold step in engineering. It is essentially of English origin and development, and its success bears witness that English engineers, though cautious, are also bold when boldness is called for. That it has fallen to members of this Institution to be leaders in so striking an innovation may, perhaps, earn a friendly tolerance for the many shortcomings of this attempt to place on record the more salient features of the system.

(To be concluded.)

PHYSICAL SOCIETY.

At the ordinary meeting of this Society on May 10, 1895, Captain W. de W. Abney, President, in the chair, Mr. HERROUN read a Paper on

"The Iodine Voltameter."

After referring to the usual methods of determining the value of the small currents used in calibrating galvanometers and other apparatus for measuring small currents, and discussing the errors to which they are subject, the author gave his reasons for selecting iodine. He did this since, with the exception of mercury in the mercurous state, iodine has the largest electro-chemical equivalent, and, in addition, by titration with sodium thiosulphate, it is possible to determine the quantity of iodine liberated with a greater accuracy than can be obtained by weighing a deposit of copper or silver with the balance. The solution employed in the voltameter contains 10 to 15 per cent. of zinc iodide. If care is taken to leave a small piece of metallic zinc in this solution, no free iodine is liberated on keeping unless the solution is exposed to a strong light for some time. The anode consists of a plate of platinum at the bottom of a tall and fairly

Digitized by Google

narrow beaker. The wire leading the current to the anode is encased in a glass tube, so that the iodine is only liberated at the bottom of the beaker, where, on account of its great density, it tends to collect. The cathode consists of an amalgamated zinc rod, which, to prevent loose particles of zinc falling down into the iodine, is surrounded by a piece of filter paper or vegetable parchment. In an electrolysis lasting for as long as two hours none of the iodine is found to diffuse up to the part of the solution near the zinc cathode. Where, on account of the extreme feebleness of the currents employed, it is necessary to allow the electrolysis to continue for longer than two hours, a U tube is used with two small plugs of asbestos at the bend, the anode being in one limb and the cathode in the other. With this form of voltameter, even after the current has flowed for several days, no signs of iodine have been found in the limb containing the cathode.

On account of the production of electric convection currents, the iodine voltameter does not seem to be quite so suitable for accurate measurements of strong currents. After the current is stopped the zinc electrode is immediately removed, the solution stirred, and the amount of iodine liberated determined by titration with sodium thiosulphate. The author finds that a convenient strength of the thiosulphate solution is one in which 1 cubic cm. corresponds to the amount of iodine liberated by 5 coulombs of electricity. This solution contains 12·8375 grammes of pure recrystallised sodium thiosulphate per litre. It is possible to perform the titration to within 0·1 cubic cm., which corresponds to 0·5 coulomb, or, if the electrolysis lasts one hour, to one 7,200th of an ampere. In a comparison made with a silver voltameter, the current as deduced from the silver was 0 0264 ampere, and that deduced from the iodine 0·0266. The author considers that part of the difference may be due to the effect of oxygen dissolved in the solution of silver nitrate.

Prof. CAREY FOSTER considered that this process for measuring currents a most valuable one. The idea of using a volumetric method for measuring currents was to him new. He did not, however, see the advantage of using a substance with a high electro-chemical equivalent if a volumetric method was going to be employed to estimate the quantity of the substance liberated. It would be possible to use a chloride, though in this case the titration would probably be less accurate.

Prof. SILVANUS THOMPSON said he thought the method would be very valuable, but he would like to know if any error was likely to arise if too great a current density was employed. The number the author had assumed for the atomic weight of silver (108) was only approximate ; if the more accurate value 107·7 were used the agreement between the results obtained with the silver and iodine voltameters would be improved.

Mr. TROTTER asked what was the largest current that could be accurately measured.

Mr. ENRIGHT said he had used porous diaphragms in iodine voltameters and found that the iodine collected in the positive compartment, while the water was driven over into the negative compartment. With strong currents it was possible to get almost pure iodine left in one compartment.

Mr. WATSON thought that, since the value for the electro-chemical equivalent of iodine used by the author was deduced from Rayleigh's value of the electro-chemical equivalent of silver, and that Rayleigh's experiments were performed in air, the difference obtained with the silver and iodine voltameters could hardly be due to the cause suggested.

Mr. ELDER warned the members that volumetric measurements were not so accurate or easy as they seemed. He particularly mistrusted a solution of sodium thiosulphate, since he had found a solution of this substance to change even in 24 hours. The difficulty of accurately reading the burette might be overcome by weighing the burette and its contents before and after the titration. The author, in his reply, said that with the size of electrodes he used (about 9 sq. cm. surface) 0·1 ampere was the maximum current it was safe to use. The only substance likely to be produced by too great a current density was periodate, which, since it was insoluble, would immediately be noticed. The influence of the dissolved oxygen was only appreciable with small currents where the electrolysis lasts some time, while in Rayleigh's experiments large currents were employed.

The CHAIRMAN, while returning thanks to the author for his Paper, mentioned that in his experience he had found zinc salts to be very untrustworthy.

Mr. A. SHARP read a Paper entitled

"A New Method in Harmonic Analysis."

The author, in this Paper, applies the principle of the form of harmonic analyser for giving direct readings of the amplitude and epoch of the various constituent harmonic terms, previously described by him, to the performance of harmonic analysis without the use of an instrument. The kinematic principle is as follows :—Let the curve to be analysed be drawn with a scale of abscissæ such that the period is 2π. Let a wheel roll on the paper and be connected with a tracing-point, P, in such a manner that as P moves uniformly in the x direction the axis of the wheel w turns uniformly counter-clockwise in a horizontal plane, and the distance rolled through during any short interval is equal to the corresponding displacement of the tracer P in the y direction. The curve traced out by w the author calls the roller curve, and from the vector joining the initial and final points of this curve the amplitude and epoch can be determined. Suppose the periodic curve consists of a portion of the curve $y = a + a_1 x + a_2 x^2 + a_m x^m$ repeated over and over again. Then if the tracer is taken round this periodic curve you get a rolled curve which may be called the first roller curve. If now the curve whose ordinates are $\frac{dy}{dx}$ is traced out, the roller curve obtained is the evolute of the first, and so on for $\frac{d^2 y}{dx^2}$, &c. The author gives two worked examples, and compares the values of the coefficients obtained with those given by the harmonic analyser of the Guilds Central Technical College.

Prof. HENRICI said he had not received the Paper in time to thoroughly master it, but he thought that, at any rate for curves where no discontinuity occurred, the relation found by the author between the roller curves was always true, the last evolute being a point and the one before that a circle. The interesting point was whether the method was capable of being used for practical purposes, for it occupied a place with respect to harmonic analysis similar to that occupied by Simpson's rule in planimetry.

Prof. SILVANUS THOMPSON asked if the author had devised a form of mechanism capable of fulfilling the kinematical conditions given at the commencement of the Paper.

The author, in his reply, said he had devised such a mechanism, and that it was described in his previous Paper. In addition, he had since invented a more practicable form, which he had patented.

The CHAIRMAN said the Society ought to congratulate itself on the large number of important Papers dealing with harmonic analysis and planimetry that had lately been communicated.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, May 24th.

Physical Society.

5 p.m. Meeting at Burlington House. Papers to be read : (1) "On Mixtures of Ethane and Nitrous Oxide," by Dr. Kuenen ; (2) "The Measurement of Cyclically Varying Temperatures," by H. F. W. Burstall.

Royal Institution.

9 p.m. Friday Evening Discourse : "The Absolute Measurement of Electrical Resistance," by Prof. J. Viriamu Jones, F.R.S.

MONDAY, May 27th.

Northern Society of Electrical Engineers.

8 p.m. Ordinary General Meeting at the Palatine Hotel, Hunt's Bank, Manchester. Adjourned discussion on Mr. J. C. Howell's Paper on "The Uses of Accumulators."

TUESDAY, May 28th.

Institution of Civil Engineers.

8 p.m. Annual General Meeting of corporate members only in the theatre of the Royal United Service Institution, Whitehall.

THURSDAY, May 30th.

Royal Institution.

3 p.m. Afternoon Lecture. "The Instruments and Methods of Spectroscopic Astronomy," by William Huggins, F.R.S.

FRIDAY, May 31st.

9 p.m. Friday Evening Discourse : "The Radiant Heat from the Moon during the Progress of an Eclipse," by the Earl of Rosse, F.R.S.

Electrical Communication with Lightships.—In a letter to the *Standard* of the 16th inst. Mr. F. Le B. Bedwell, R.N., referring to Mr. F. Higgins' letter claiming that the "Sunk" method was designed and recommended by him in 1881, a claim to which we called attention last week, states that this is a most unfounded claim. Mr. Higgins' plan is, says Mr. Bedwell, on an entirely different principle, and has not the remotest resemblance to the method now in use, viz, a Bedwell swivel and apparatus known as the "Sunk" system.——In reply to Admiral Field, Mr. Bryce stated in the House of Commons on Monday that, in addition to the works recommended in the recent Report of the Royal Commission, there were still some works, recommended in the first report, which had not yet been carried out. A sum of £11,000 had been placed at the disposal of the Board of Trade for the purpose of effecting electrical communication with light vessels, &c., during the present financial year, and the Board were at present considering on which of the works recommended that amount—which was not sufficient for all—should be expended.

The Electrician.

(The Oldest Electrical Journal, 1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny. Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	YEAR.	HALF-YEAR.	QUARTER.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* **4** *p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of*—

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation.*

SPECIAL NOTICE.

Owing to the growth of the electrical and allied industries the demands for space in "THE ELECTRICIAN" are, for the greater part of the year, so pressing that a permanent increase in the size of the journal has become necessary. To meet the increased cost involved by this step, and by other improvements, such as heavier paper and more numerous illustrations, the price of "THE ELECTRICIAN" has from May 3rd been advanced to 6d.

The Subscription to "THE ELECTRICIAN," commencing with Vol. XXXV. (May 3, 1895), is as follows:—

	YEAR.	HALF-YEAR.	QUARTER.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

A POORLY-CULTIVATED FIELD OF RESEARCH.

If science consists, not merely in the mechanical observation of phenomena, but in the co-ordination and correlation of facts, and if a fair test of the completeness of this co-ordination and correlation be the accuracy with which a given result may be predicted as certain to follow from a given set of conditions, meteorology, and with it atmospheric electricity, must be held to be, even at this late hour of the day, hardly within the scientific pale. Nothing strikes anyone who has dealt all his life in ohms and volts and amperes with more astonishment, when he passes from the well-ascertained laws and super-accurate measurements of physics, than the chaotic state in which the foundations of meteorology still remain, and the comparative crudity of the apparatus with which atmospheric conditions continue to be gauged. And when we come to apply the test of arguing from ordinary everyday phenomena to the consequences that will ensue, the dubious nature of the claim of meteorology to be considered a science is even more apparent. "No important rules," says Mr. THOMAS RUSSELL in his recently published work, "have ever been formulated as the result of the investigations of cloud forms as indicating weather changes or approaching storms, and yet every observer and predictor makes use of them." Again, towards the end of his book the author winds up his chapter on weather predictions by the truly mournful, or it may be unduly modest, statement that "the most that can be said in the way of prediction is, that the rain will continue for some indefinite time at places where it is already raining": as he sardonically remarks, as much as this "can be said on general principles, on the ground of probability, without the aid of a weather map." But though they have not as yet endowed us with a science, our modern meteorologists have spoiled us of our ancient superstitions. The time-honoured belief that forests have not a little to do with increasing the rainfall in their vicinity is, we are told, "to be relegated to the infinitely little things of

Digitized by Google

meteorology;" whatever that may mean; likewise we are forbidden to put our trust in the twinkling of the stars, the ruddy glow at sunset, or the transparency of the air as reliable indications of approaching rain. In short, we have been deprived of our inbred meteorological instincts, and have not as yet been provided with any rigid rules in their stead. Hasty generalisation is, of course, to be deprecated, but meanwhile this state of transition is somewhat perplexing.

A perusal of the lecture by Prof. Schuster on "Atmospheric Electricity," which will be found in another column, will reveal tolerably clearly the existence of much the same state of "glorious uncertainty" in a branch of electrical science closely allied to meteorology. The clearing up of the enigma of the origin of atmospheric electricity could hardly fail to throw light on the still more important problem, the nature of electricity itself; yet it cannot be said that we have made appreciable advance in this direction. The theory originally propounded by Peltier that the earth possesses a permanent negative charge is indeed a simple one, explaining many facts; but it gives us no clue as to the source of this charge, although the recent observation of Lenard that every sea wave breaking into spray under the action of a strong wind leaves the water negatively electrified might be turned to account. Again, in a recent lecture, an abstract of which we published on May 10th, Lord Kelvin stated his belief that "the rain itself is the real restorer of the normal fair weather positive (of the air). Rain or snow, condensing out of the air high up in the clouds, must of itself become positively electrified as it grows, and must leave positive electricity in the air from which it falls." But, as Prof. Schuster points out, this permanent charge view rests on the assumption that the earth is perfectly insulated, or that gain and loss of charge are equilibrated by some means as suggested above. As regards space, it may be so insulated; as regards the lower regions of the atmosphere, it certainly is not; every column of ascending hot air, every lightning flash, undoubtedly helps to dissipate the terrestrial charge, and the ultra-violet rays in all probability also assist. But, assuming the permanency or the equilibrium of the negative charge, where is the positive? The observations of Dr. Baschin, and those made on the Sonnblick, seem to point towards the existence of a layer of positively electrified air some 10,000ft. or 15,000ft. above us—that is to say, just below the level of the lowest cirrus clouds. On the other hand, the existence of cloud formations at much higher altitudes (25,000ft. to 50,000ft.) and the phenomenon of the aurora at still greater heights do not tend to corroborate the idea that, electrically speaking, the world comes to an end at a few thousand feet above the ground. We are, therefore, in this position: we have a bare clue as to the origin of the earth's supposed negative charge, and we have "provisionally established that the lines of force of the normal electric field of the earth end within the first 10,000ft. or 15,000ft." But we are still without an entirely satisfactory theory connecting the daily double maxima of potential gradient with the coincident barometric maxima; we are still, in spite of Prof. Schuster's ingenious suggestion of a sort of "replenisher" action, without any complete explanation of the generation of the enormous differences of potential apparently necessary to account for lightning discharges; we are still quite unable to connect alterations in the potential gradient with weather phenomena, on the other hand we know all manner of curious little facts, and "it is quite likely that there is some truth" in the various theories propounded to fit them. As Prof. Schuster rightly remarks, what is wanted now is a series of continuous observations on the same plan by means of recording instruments, which, we would add, should be situated in various parts of the world, and at various distances from and heights above sea-level; the co-ordination of the observations being undertaken by a properly constituted central bureau. England, with its many possessions in both hemispheres, would seem to be specially called upon to aid the good work of educing something approaching order out of something not unlike chaos.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(Continued from page 89.)

39. Mance Test for Fracture: Kennelly's Modification.— When a cable is fractured the resistance of exposure is usually very different at the two broken ends. Therefore, it is no use comparing results from both ends, even though a duplicate cable permits of the results being communicated. Each end must independently localise position of break, and the ship when it cuts in depends only on tests on board. Now, as stated above, the Mance test from one end only gives the resistance up to fault, plus something less than the true resistance of fault. Without some means, therefore, of eliminating the resistance of the break, the test is not satisfactory.

Mr. Kennelly has shown (*Electrician*, Oct. 14 and 21, 1887) that it requires *three* observations from one end only to eliminate resistance of break, and he takes three readings on the bridge to instrument zero with different currents to line.

The current is varied by resistance in battery circuit, taking the first reading with a fairly high resistance, and then reducing it so that the current in the second reading is, say, four times, and in the third reading nine times, that in the first. The battery should be a low resistance one and of 30 or 40 volts. Key clamped down zinc to line. Let A, B, and C be the readings on the bridge for a set of any three different currents, C being the balance with the largest current and A with the least. When these currents are in the proportion of 1:4:9 the formula for distance of break is

$$\frac{A+C}{2} - 4\,(B-C) \text{ ohms.}$$

When they are in the proportion of 1:4:16 the formula becomes

$$\frac{A+2C}{3} - 2\,(B-C) \text{ ohms.}$$

If anything the readings with ratio 1:4:16 gives the most accurate results. It is well to take a series of readings with different currents from one up to, say, 40 milliamperes, sufficient to provide for a few sets of each. The resistance to add to the battery for a given current in milliamperes to flow to cable can be calculated very closely. The first approximation is

$$\frac{500\,E}{\text{Number of milliamperes}} - \left(b + \frac{a}{2}\right) \text{ ohms,}$$

where b is the battery resistance, a is the resistance of one of the proportion arms of the bridge, and E is battery E.M.F. With this inserted we get a preliminary balance on the bridge. The correct resistance is then the above, reduced by half the balance so obtained.

The added resistance then being corrected accordingly, the correct result is obtained by readjusting the balance. Four sets, each of 1:4:9 and 1:4:16 proportional currents, can be obtained by the eighteen currents given in the Table on next page, for each of which is worked out the first approximation to the added resistance, taking as an example:

E.M.F. of battery	= 50 volts.
Resistance of battery	= 120 ohms.
Bridge arms........................	100/100.

The first approximation to the added resistance is then:—

$$\frac{25{,}000}{\text{Number of milliamperes}} - 170 \text{ ohms.}$$

* Copyright. All rights reserved.

Digitized by Google

The approximate resistance in the second column is added to the battery, and a balance obtained, which is entered in the third column. Then, the added resistance having been reduced by one-half the balance so obtained, a second and final balance is obtained, which is the correct result. This is entered in the fourth column.

Milliamperes to line.	First approximation added resistance.	Balance, with approximate added resistance.	Final balance, with corrected added resistance.
1	24,830		
1½	16,496		
2	12,330		
2½	9,830		
3	8,163		
4	6,080		
6	3,996		
8	2,955		
9	2,607		
10	2,330		
12	1,913		
16	1,395		
18	1,220		
27	758		
32	614		
36	525		
40	457		

It is not desirable to go above 40 milliamperes, as the heating effect on the low resistance coils of the bridge may injure the insulation. With the above series of balances we have the following choice of combinations.

For ratios of 1:4:9 the following four sets:—

1: 4: 9
2: 8:18
3:12:27
and 4:16:36

For ratios of 1:4:16 the following four sets:—

1 : 4:16
1½: 6:24
2 : 8:32
and 2½:10:40

For these ratios the two formulæ given above for distance of break are applied respectively.

In this formula Mr. Kennelly has taken into account the variation in resistance of the fault with the different strengths of currents used. That is, on the basis of the law which he established by experiment—that the resistance of an exposed conductor varies as the square root of the current. This law, however, was not found to hold good in exposures under a certain limit, which may be roughly stated as half a square centimetre; and, therefore, the formula is not strictly correct for fractures with small exposures. Another cause of error, also prevalent in the foregoing Mance tests, is that the polarisation current increases as the testing current is increased, whereas the formula assumes it to remain constant.

The effect of these two sources of error is least apparent in the result when the current used in the third balance largely exceeds that in the second.

Another convenient way of calculating the resistance to add to the battery for various strengths of current through the break is as follows: The actual value of the currents in milliamperes need not be known, so long as there is the required ratio between them, and the largest current used does not heat the bridge coils. Generally speaking, currents up to 50 milliamperes may be used with safety, but it depends upon what proportional coils are used in the bridge arms. Any small current is taken to start with (the actual strength of which need not be known), and resistances are adjusted in the battery circuit to give multiples of this current. Say a balance has been obtained on the bridge to instrument zero with equal ratios (each ratio arm being a ohms) and a battery of resistance b, to which has been added a large resistance ρ. The resistance unplugged to balance is, say, A ohms.

Now, to obtain a current to line of n times the strength of the above the resistance added to the battery must be less than at first. This resistance evidently depends upon the resistance unplugged to balance, and, consequently, a trial test has to be taken first with an approximate estimate of this resistance, which is

$$\frac{2\rho + A - (n-1)(2b+a)}{2n} \text{ ohms.}$$

Putting this in circuit with the battery, a balance is obtained, and then the approximate resistance is reduced by half the amount unplugged to balance. This correction being applied, we have the right resistance in circuit to produce n times the current to line, which gives the balance reading B.

By a similar process we obtain the balance reading C, and then apply the values of A, B, and C to the formulæ given above and obtain distance of break. For instance, suppose that for the first reading A we put 10,000 ohms in circuit with the battery, the latter having 50 ohms internal resistance. With a ratio of 100/100 the bridge is balanced, say, with 900 ohms unplugged.

Here $b = 0{\cdot}50$; $\rho = 10{,}000$; $a = 100$; and $A = 900$.

Now we require to obtain the readings B and C with, respectively, four and nine times the current used in obtaining A.

The resistance to add to the battery for four times the current ($n = 4$) is, approximately:—

$$\frac{20{,}000 + 900 - 3\,(100 + 100)}{8} = 2{,}537 \text{ ohms.}$$

With this resistance added to the battery (instead of the 10,000 ohms) a balance, say, of 820 ohms is obtained. Reducing the resistance of 2,537 ohms by half of 820, we have the right amount of resistance to give four times the current. The bridge is then balanced again, giving, say, 800 ohms (B). For nine times the current ($n = 9$) the added resistance is approximately,

$$\frac{20{,}000 + 900 - 8\,(200)}{18} = 1{,}072 \text{ ohms.}$$

With this resistance in circuit the balance is, say, 730 ohms. Then, reducing the resistance of 1,072 ohms by half of 730 we obtain the balance (C), say, of 700 ohms. Then

$$\text{Distance of break} = \frac{A + C}{2} - 4\,(B - C)$$

$$= \frac{1600}{2} - 400 = 400 \text{ ohms.}$$

For the ratios of current of 1:4:16 we should have to take a reading with 16 times the current. The approximate resistance to add for this current ($n = 16$) is

$$\frac{20{,}000 + 900 - 15\,(200)}{32} = 560 \text{ ohms.}$$

With this resistance in circuit the balance obtained is, say, 650 ohms. Then, reducing the resistance of 560 ohms by half of 650 we obtain the balance (C), say, 640 ohms. Then

$$\text{Distance of break} = \frac{A + 2\,C}{3} - 2\,(B - C),$$

$$= \frac{900 + 1{,}280}{3} - 2\,(160),$$

$$= 727 - 320 = 407 \text{ ohms.}$$

By starting with other resistances instead of 10,000 ohms, the unit current can be varied and the resistances to insert for 4, 9, or 16 times the unit current can be found in the manner described, so that as large a range of currents as desired can be used.

(To be continued.)

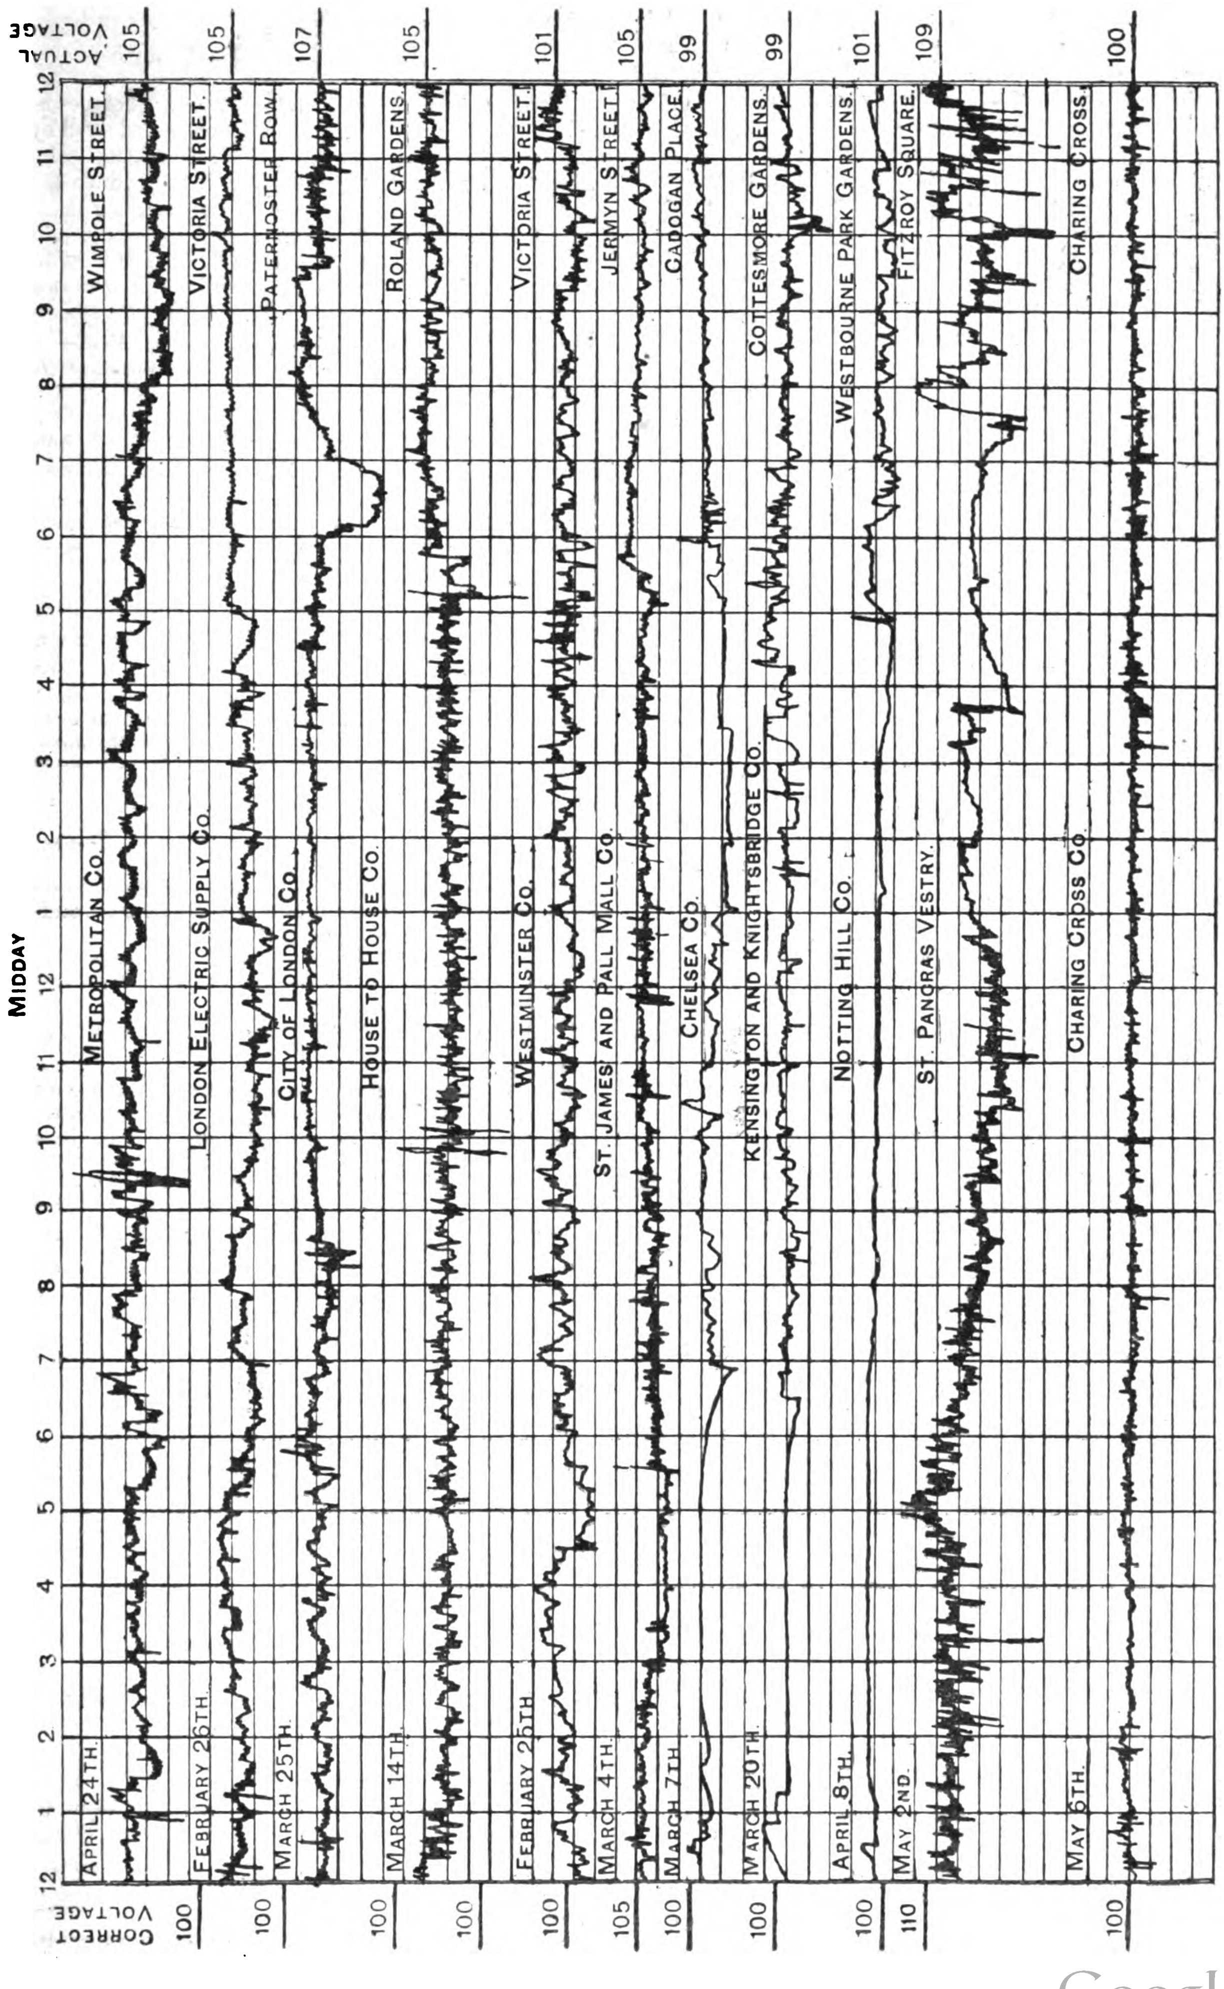
VARIATIONS OF ELECTRICAL PRESSURE IN LONDON.

BY A. A. C. SWINTON.

The accompanying diagram has been prepared from records obtained with Major Holden's form of hot-wire recording voltmeter. This instrument is exceedingly sensitive, and at the same time very dead beat in its action, and the fluctuations shown on the diagram consequently very accurately represent the actual fluctuations in the electrical pressure in each case.

Digitized by Google

DIAGRAM SHOWING VARIATIONS IN ELECTRICAL PRESSURE.



In order to ensure correctness, the recording voltmeter was from time to time checked with an Evershed voltmeter, which in turn was calibrated through the kindness of Major Cardew at the standardising laboratory of the Board of Trade.

As will be observed, all the chief London companies, as also the Vestry of St. Pancras, are represented, mention being made of the dates and localities where the records were taken. In the diagram in each case the curve represents the electrical pressure from midnight to midnight, the horizontal lines being drawn at a distance apart corresponding to two volts. On the right-hand side of the diagram are marked the actual volts of each curve at that point, while on the left-hand side are marked the correct voltages that the several undertakers claim to supply.

It will be seen that in many cases the variation from this correct voltage is considerable, being much more than is compatible with the regulations of the Board of Trade, the comfort of the consumers, or fair play to the lamps. It will be observed that so far as fluctuations from the average are concerned there does not appear to be much to choose between the alternating and the continuous-current systems of supply; but it will be noticed that while with continuous currents there seems to be in some instances a tendency for the average volts to be below the correct voltage, with the alternating current it is the other way, and the average volts supplied are in each case very considerably higher than they should be. Where the supply is maintained by accumulators during some portion of the 24 hours, this is well indicated by the smoothness of the curve.

The writer is, of course, well aware that a single record on a particular date taken in only one locality cannot be considered as in any way a fair criterion of the uniformity of any supply; still, undertakers should maintain a uniform pressure in all parts of their area of distribution and at all times. Consequently, while the fact that a certain amount of luck may enter into the reason of the record of one undertaker being better than that of another should prevent undue elation on the part of those whose curves are best, it is hoped, on the other hand, that the publication of these records will have the effect of stimulating those undertakers whose curves show the greatest variations to the attainment of a more uniform pressure.

THE BUREAU DE CONTROLE DES INSTALLATIONS ELECTRIQUES.

The numerous accidents caused by the defective installation and careless management of electric lighting plants, as well as the frequent complaints received by electric supply companies from their customers relating to their meters, called for the necessity of organising an official "Bureau de Contrôle des Installations Electriques," free from any commercial connections, and having for its object the inspection of electric lighting installations, and the testing of meters belonging to electric supply companies and private concerns, also providing to its customers all the desired information concerning the safe operation of their installations. The Société Internationale des Electriciens proposed to meet this want by arranging the "Laboratoire Centrale," on the lines of the Physikalische Reichsanstalt of Charlottenburg, but the "Laboratoire" having confined its work almost exclusively to measurements of high precision, and the testing of instruments brought there, the field remained open for an office answering the above mentioned purpose of inspecting and controlling private and public lighting installations. In view of these facts, the Syndicat Professionnel des Industries Electriques resolved to organise such an institution. The insufficiency of funds, however, obliged them to make a call upon the generosity of its members in order to supply the necessary money to make a start with. The electric supply companies, worried by the very often unjustifiable complaints of their customers, gladly contributed; other donors answered the call, and the sum of 34,000fr. was collected, as follows: Compagnie de l'Air Comprimé, 4,000fr.; Compagnie Edison, 4,000fr.; M. Fontaine, 2,000fr.; Maison Breguet, 2,000fr.; Maison Menier, 4,000fr.; Sautter, Harlé, and Co., 2,000fr.; Schneider and Co., 2,000fr.; Secteur des Champs Elysées, 4,000fr.; Secteur Place Clichy, 4,000fr.; Société d'Eclairage et du Force par l'Electricité, 4,000fr.; Chambre Syndicale des Industries Electriques, 2,000fr. This amount allowed the Syndicat Professionnel des Industries Electriques to organise the Bureau de Contrôle, which began work on February 15, 1893, under the direction of M. R. V. Picou, the well-known consulting engineer, who agreed to manage the office on the following lines, proposed by the Syndicat Professionnel des Industries Electriques:—

(I.) The objects of the Bureau de Contrôle are:—(1) To insure the periodic control of its clients' installations in order to prevent any damage likely to compromise the security of the said installations; (2) to inspect installations at the request of any interested party; (3) to furnish all information, technical, commercial, legal, or official concerning installations, central stations, or any other electrical concern.

(II.) The work of the Bureau de Contrôle consists in calls made on the customers with a view of inspecting their installations; these calls are made by special men, or inspectors, who communicate to the customers the result of their inspection.

(III.) Although the Bureau de Contrôle is placed under the "patronage" of the Chambre Syndicale des Industries Electriques, who elect its manager and discuss its regulations, the establishment is entirely independent, the manager alone being responsible.

(IV.) In order to ensure impartiality, the manager of the Bureau de Contrôle is forbidden to act as a contractor or manufacturer of electrical supplies, or to take any interest whatever in a firm undertaking installations or the construction of electrical apparatus.

(V.) The Bureau de Contrôle agrees to give its clients two inspections of their installations per year. These inspections always include testing of the meter or meters, and are carried out without any preliminary notification, and at a minimum interval of five months or a maximum of seven months. The inspectors receive orders to give all necessary information to ensure the proper working of the installation. Every inspection is followed by a written report to the customer giving a statement of the general condition of the installation, and calling his attention to the special points necessitating modifications.

(VI.) In case of accident, the customers are requested to at once advise the manager, who immediately calls or sends an inspector to investigate the matter. This visit is always gratuitous.

(VII.) The customer is bound to inform the manager of the Bureau de Contrôle of any addition, modification, or repairs he intends to carry out in his installation.

(VIII.) The customers of the Bureau de Contrôle pay for the two regulation visits a fee mentioned hereafter.

(IX.) Beyond the regulation visits, the customer may demand supplementary inspections of his installation as often as he may think necessary, these supplementary visits to be charged for as mentioned hereafter.

(X.) The officers of the Bureau de Contrôle are, moreover, at the disposal of their clients and to people at large for the execution of work, such as testing of dynamos and storage batteries, testing of meters or measuring apparatus, this, of course, to be charged for according to regulation.

(XI.) The Bureau de Contrôle holds at the disposal of its customers all information relating to electrical installations. At their request, the office will furnish them a copy of such information for a charge agreed upon with the manager.

(XII.) The manager submits to the approval of the Chambre Syndicale each year the accounts of the preceding year, and sends in a report on all the work of the office. The report and the resolution are printed in the Directory of the Syndicate, and sent gratuitously to all clients.

(XIII.) Any owner of an electric installation who desires to subscribe to the Bureau de Contrôle, must fill and sign a policy in accordance with the regulations. Subscriptions commenced during the first six months of the year have to be paid in full. If the subscription is made subsequently to July 1st, the charge is made only for the remaining six months.

(XIV.) The regulation charges are as follows:—

(*a*) The annual subscription is based on the number of incandescent lamps in the installation, each arc lamp being equivalent to five incandescent lamps, and each motor or dynamo being equivalent to 10 lamps.

For less than	10 lamps	charge	5fr.
From 10 to	20	„ „	0·50 c. per lamp.
„ 20 to	23	„ „	10·0fr.
„ 23 to	50	„ „	0·45 c. per lamp.
„ 50 to	56	„ „	22·50fr.
„ 57 to	100	„ „	0·40 c. per lamp.
„ 100 to	115	„ „	40fr.
„ 116 to	200	„ „	0·35 c. per lamp.
„ 200 to	233	„ „	70fr.
„ 234 to	500	„ „	0·30 c. per lamp.
„ 500 to	600	„ „	150fr.
„ 600 to	1.000	„ „	0·25 c. per lamp.
„ 1.000 to	1,250	„ „	250fr.
Above 1,250		„ „	0·20 c. per lamp.

(*b*) The fee for supplementary visits one-third of the annual charge, with a minimum of 5fr.

(*c*) Fee for inspecting special parts of an installation, meter testing, 20fr. Supplementary fee for work done under Article X., attendant for one day, 30fr.; ditto, half a day, 20fr.

Digitized by Google

(*d*) Fee for inspections of installations, for non-subscribers, two-thirds of the corresponding annual subscription, with a minimum of 5fr.

(XV.) The above charges are for the Department of the Seine; for other Departments the travelling expenses incurred by the manager or the inspector must be borne by the subscriber or subscribers.

(XVI.) The above regulations have been discussed and approved by the Chambre Syndicale des Industries Electriques, at their Board meetings of February 7, 1893, and February 5, 1895. They are subject to revision at the end of each year, as per decision of the Chambre Syndicale.

At the end of the first year the number of subscribers to the Bureau de Contrôle was 46, representing 13,276 glow lamps. The results of the inspections of electric installations and of the testing of meters were as follows:—

Installations inspected		101
Installations reported as being defective—		
With regard to insulation	23	
With regard to electric fittings	21	
With regard to putting up	18	
		62
Meters tested		77
Meters recorded as being defective		19

During the second year of operation, the Bureau de Contrôle secured 45 new customers, representing 7,000 lamps.

The following results were obtained by inspections and tests:—

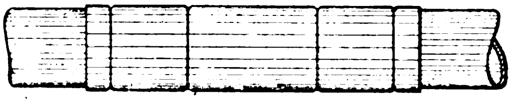
Installations inspected		168
Installations reported as being defective—		
With regard to insulation	40	
With regard to electric fittings	71	
With regard to putting up	37	
		148
Meters tested		172
Meters recorded as being defective		43

At the present time the Bureau de Contrôle numbers 110 customers, representing about 22,800 lamps. At the end of second year of his management M. Picou asked to be relieved of his duties, his time being very much taken up by his work as consulting engineer. His resignation was accepted, and M. Gaston Roux, electrical engineer, was chosen by the Chambre Syndicale on February 15, 1895, to take M. Picou's place for 10 years. Under the new management of M. Roux the organisation of the Bureau de Contrôle has been modified, in order to develop the operations. The office has been transferred to 12, Rue Hippolyte Lebas, agents have been appointed, and arrangements with insurance companies are being negotiated. M. Roux's belief in the prosperity and extension of the Bureau de Contrôle is so great that he has pledged himself, in taking its management, to return to the Chambre Syndicale the 34,000fr. given by them towards the organisation of the office. The operations of the Bureau de Contrôle are at present confined to Paris only, but the new manager hopes to extend them to the principal manufacturing and residential towns of France. In another article we hope to describe the method employed for testing the meters and insulation of installations.

INTERIOR CONDUIT WIRING.

A system of interior conduit wiring, the invention of Mr. E. H. Johnson, and for some time past used by the Interior Conduit and Insulation Company, of New York, has recently been introduced into this country, and was briefly noticed in our issue of March 29th. The system consists in wiring through a series of insulating tubes which can be laid throughout a house in the manner of gas or water pipes. Into these tubes the wires for single, double, or three-wire systems can be drawn; the basis of the system is, therefore, an insulating tube. This is now made in three grades, the plain tube, the brass covered, and the iron armoured. The plain tube is waterproof and electrically fireproof, but in order to protect from external sources of fire, an extra mechanical covering of brass or iron is sometimes used. The insulating material of the tube consists of paper impregnated with a suitable compound which will render the tube incombustible and also gives it a sufficiently smooth surface, and strength and toughness enough for the work it has to do. In order to retain the tubular form the walls of the tube are built up spirally, and the complete tube, after a further cementing treatment and impregnation in and outside, with a waterproof compound, becomes almost homogeneous in texture. In some cases it has been found that the tube will stand being embedded in cement, but where caustic cements occur brass-covered tubes are usually used. It will be seen that in addition to the insulation of the wires themselves, the material of the tube assists the insulation resistance, giving much better results than with ordinary casing. These tubes are supplied in standard 10ft. lengths, with one end ready fitted with a coupling socket. They

Fig.



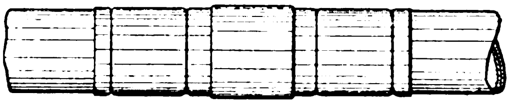


Fig. 2.

are made in standard sizes from ½in. to 2½in. diameter. Fig. 1 shows the ordinary form of coupling socket, and consists of a thin metal sleeve. The end of the tube to be joined on is first cut square with an ordinary hand saw, and then reamed inside and out with a suitable reaming tool. The end is then slightly warmed over a small flame so as to soften the outside waterproof compound, and, as this causes the tube to shrink, it may easily be slipped into the sleeve until it presses against and unites with the end of the other tube, thus making a sealed

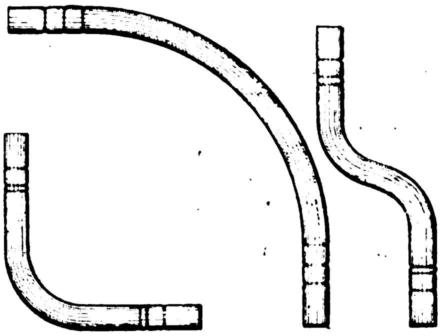

Fig. 3.

joint. This done, two rings in the soft metal sleeve are indented by means of a pair of clamping pliers, thus gripping the sleeve to the tube. For the brass-covered tubes the joint operation is practically the same, except that the brass has first of all to be cut back by means of a trimming tool. Fig. 2 shows a coupling for such a joint, and in this case the ends of the tubes are covered with an internal insulating sleeve at the point of abutment. It is stated that such joints may be made in less than half a minute. In order to meet the requirements

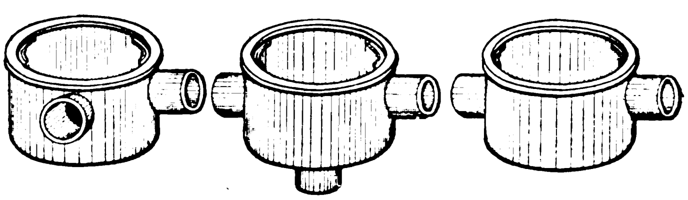

Fig. 4.

of practice a series of standard bends and elbows and junction boxes, or fishing boxes as they are called, are regularly manufactured. Fig. 3 shows some of these bends and elbows, and Fig. 4 a number of fishing boxes. If there are only three or four elbows on a length of conduit it is the custom to draw the branch wires right through, but when more than this number of bends occur a fishing box is inserted so as to form a convenient point from which the wires can be drawn out and redrawn

Digitized by Google

into the next section. These boxes are also used in turning abrupt corners. Moreover, the box method would be favoured where the tubes are between floors or accessible on the surface, whilst the elbow method is followed where the work is to be completely plastered up. The fishing wire consists of a narrow band of steel fitted with brass ends, and by means of this device a long string or cord can be drawn through the system of tubes after erection and the wires for the different circuits drawn through and connected up. It is sometimes found advisable to assist the drawing-in process by blowing powdered soapstone through the conduits, the effect of this material being to reduce the friction and to diminish the chances of abrasion of the insulated wires. To secure the tubes in position wire or strip fasteners or pipe nails are used according to the local condition. Fig. 5 shows a method of wiring a bracket when the wires drop from the floors above, provision being made at the same time for the insertion of the controlling switch below the bracket. The usual method of arranging a conduit system is as follows: The work is laid out first of all in sections, or in the case of very large buildings in a number of sections. Each section should be fed by a vertical riser, which may pass through several floors. By this means any one floor is supplied with two or more independent risers, upon which cut-out bars from several centres of distribution are arranged. These distributing boards are, as a rule, placed in corridors, the fuses being generally bunched together; and it is claimed that this arrangement has the advantage of avoiding a multiplication of elbows and inter-section boxes. Fig. 6 is a diagram of one possible arrangement of the lines of a single branch circuit, and in this extreme case independent switches are supposed to be required at every lighting point. It will here be seen that although a separate tube is advocated for each of the main wires or risers, when the branch wires radiate from the cut-out board, with less than 10 to 12 amperes on them, it will be safe and practicable to draw them together into one tube, care being taken to protect each branch circuit by double-pole fuses. One of the advantages claimed for this system is that when any one wire fails it can be withdrawn from outlet to outlet and a new wire substituted without interfering with the walls or ceiling to which the tubes may be attached. In addition, its advocates maintain that the fact that a complete system of tubes can be laid throughout a building during its construction, after the manner of gas or water tubes, is of itself sufficient to justify such a system being adopted, even if it possessed no other merits. In conclusion, we may observe that the interior conduit wiring system is not new to Europe, but that four years ago the system was inaugurated in Germany. We understand that it is used in the palace of the Empress Frederick, and that it has been adopted by such firms as Messrs. Siemens and Halske, Schuckert, Peiper, Bréguet, Pitot, Maschinenfabrik-Oerlikon, and the Helios Company, so that the system appeals to the English market more strongly than a complete novelty would be able to do. Arrangements have now been completed for the introduction of this type of work into England under the auspices of the General Electric Company and Mr. F. Bathurst.

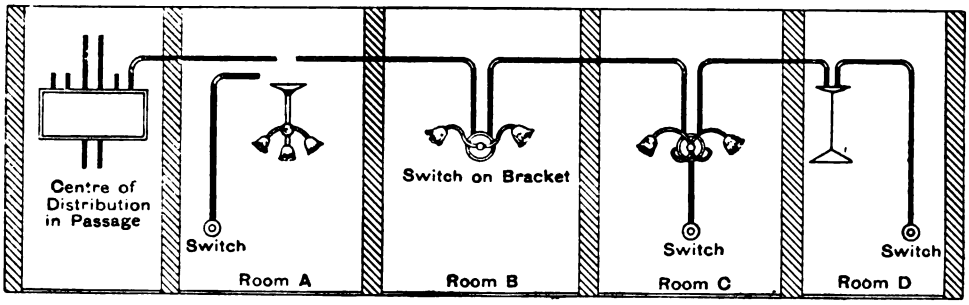

Fig. 6.

ELECTRIC LIGHTING TROLLEY.*

The first form of trolley used in connection with the system for lighting by electricity the cable cars on the New York and Brooklyn Bridge has been abandoned. This form was similar to the ordinary type of trolley with the length of pole reduced to about 2ft.

It was found that the wheel would not follow the wire, owing to the shortness of the pole and the thrust of the car at switches.

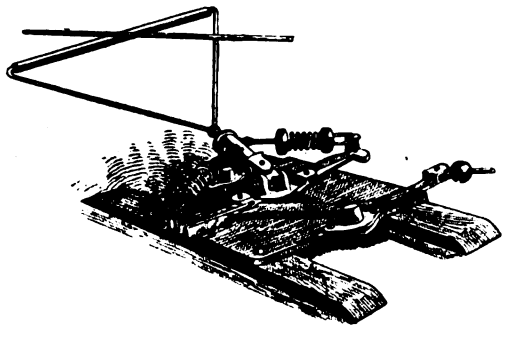

Fig. 1.—Trolley Used for the Electric Lighting of the New York and Brooklyn Bridge Cable Cars.

The form of trolley shown in Fig. 1 is now in use. It consists of a triangular wire frame, which is held in the pole socket of the trolley base. The upper part of the frame, which is pressed against the wire, carries a brass roller 18in. long. The contact thus effected, partly sliding and partly rolling, seems to meet all the requirements. The plan of reversing the trolley at the terminals at first consisted in merely raising the wire gradually until the trolley could stand upright, when it was thought it would reverse itself as the car changed its direction. In practice it has been found necessary to add the swinging stirrup shown in Fig. 2, which trips the trolley as it passes under it.

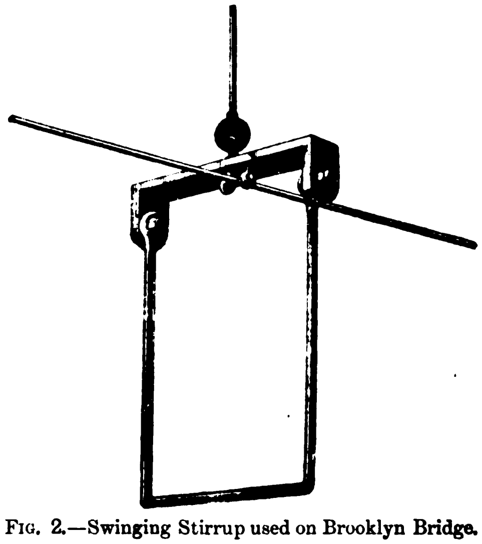

Fig. 2.—Swinging Stirrup used on Brooklyn Bridge.

PARLIAMENTARY INTELLIGENCE.

SELECT COMMITTEE ON THE TELEPHONE SERVICE.

The Telephone Committee held another sitting last Tuesday, the Postmaster-General being in the chair.

The first witness was the Hon. J. G. WARD, the Postmaster-General of New Zealand. In reply to the Chairman, he said he had been Postmaster-General for about five years, and during that time had had practical control of the telegraphs and telephones, both of which were in the hands of the State, the Colony having legislated to prevent anyone else from introducing a telephonic or telegraphic system. The telephonic system in New Zealand had worked very successfully, and its development over a sparsely-populated country had been very marked. At the starting of the system, 12 years ago, there were 116 subscribers ; now there were nearly 5,000, or about one subscriber per 120 inhabitants. Four-fifths of those subscribers would be urban, but the system was extended very widely from one end of the country to the other. The connecting trunk wires were used for both telegraphic and telephonic purposes. With one or two exceptions they used a single wire everywhere, and they changed from the one system to the other as the necessities of the public required. They charged a subscription of £5 per annum for business purposes if the subscriber was within half-a-mile of the exchange, and for private houses if within a mile of the exchange, but beyond those distances extra charges were made. Anyone requiring an exchange beyond a distance of five miles from an already existing exchange had to give a guarantee to keep the instrument for five years. In each town they had only one central exchange, but in addition to those exchanges they had bureaus, which are equivalent to the English call offices, at points all over the town. The total cost of the system from the beginning to the end of the last financial year was £104,500, and the total earnings £183,800. After allowing 5 per cent. for depreciation and 5 per cent. interest on capital, there was a net profit left of £54,000, which was handed over to the Consolidated Fund of the country. Every expense they had incurred was charged against the telephones, but where the exchange was situated in a Government building, the telephone accounts were not debited with rent. In New Zealand they were opposed to a system of centralisation, and at Wellington, where there had been a considerable increase in the number of subscribers during the last year or two, they were proposing to build an independent exchange a mile and a-half distant from the existing one, and to connect it with the trunk wire rather than have one very large exchange.

By Sir James Fergusson : The new works were partly paid for out of revenue. The greatest number of subscribers on any one exchange was returned as 872 on March 31, 1894, at Wellington, but that number had probably now risen to 1,200. Their longest line of trunk wire for telephoning purposes was about 100 miles, but they spoke over a distance of 150 or 180 miles. The service was an efficient one, and they had very few complaints, but he admitted that the single-wire system was not as good as a metallic circuit.

By Sir Charles Cameron : At the exchanges non-subscribers were charged 6d. for three minutes' conversation, if for less than six miles, and 1s. for over six miles ; and subscribers paid 6d. for six minutes. In Wellington there were 1,000 telephone users, and the population was 45,000 ; and in Auckland, with a population of 70,000, there were 726 subscribers. No reward or recognition was given to the telephone inventors when the State legislated to secure the monopoly. They had no difficulty whatever as to wayleaves, as that had been provided for by legislation. They worked on the pole system with overhead cables.

Mr. W. H. DICKINSON, Deputy Chairman of the London County Council, recalled, said that the County Council had sent out a circular to the subscribers of the National Telephone Company, numbering 7,359, calling their attention to the sittings of the Telephone Committee, and asking them to state whether the "existing service is sufficient and satisfactory ; if it is not satisfactory, in what respects is it unsatisfactory ; and what suggestions, if any, you would make for the improvement of the service." That circular was dated May 6th. The total number of replies received was 2,536 ; of those 555 expressed entire satisfaction, and 1,981 were not thoroughly satisfied. Of these 1,981, 1,305 expressed general dissatisfaction, 350 were undecided in opinion, but made no suggestion for the improvement, and 326 expressed themselves satisfied, but suggested improvements. About the same time the Company sent out a somewhat similar paper, and some of the replies were sent to the County Council instead of to the Company.

At the conclusion of his evidence, Mr. DICKINSON expressed his regret that Mr. Bennett, whom the Council had proposed to call, was very ill, and unable to attend ; but stated that he was quite prepared to put in the figures which had been prepared by that gentleman, showing the cost of various telephone systems, if the Committee desired it. The Chairman, however, declined to accept these figures, as they could not be cross-examined to.

Mr. JAMES STAATS FORBES, the President of the National Telephone Company, was the next witness. He said he would deal first with the document which the Company sent out to its subscribers on Friday, May 3rd. In that document they asked their subscribers to state whether they approved of the service being undertaken by the London County Council, and whether they were satisfied that the service supplied by the Company was reasonable ; 2,346 subscribers stated unconditionally their satisfaction with the service ; 266 stated their satisfaction, with qualifications ; 43 signed in favour of the London County Council, and 36 were returned as refusing to sign. So that, on the point of numbers the Company rather headed the County Council. Mr. Forbes then dealt with the history of telephony. He informed the Committee that Bell's Patent (4,765), which was dated December 9, 1876, expired on December 9, 1890 ; and that Edison's Patent (2,909), which was dated July 30, 1877, expired on July 30, 1891. On May 13, 1880, the Bell and Edison Companies amalgamated, and started business as the "United Company." On December 20th, in the same year, judgment was given in the Post Office action, declaring a telephone to be a telegraph, and therefore covered by the Post Office monopoly. In accordance with the statement of the Attorney-General (Sir Henry James), that the object of the Postmaster-General was not to prevent telephony, but to assert privileges, and that he would be willing that the Company should work on under a licence or agreement, a licence was granted to the United Company on April 11, 1881. That licence expired on December 1, 1884 ; and a second licence was granted to the Company on November 29, 1884. The first licence was over very restricted areas, namely, five miles round London, and one or two miles round a certain number of other centres. The result of the first licence was, to absolutely restrict and suppress telephony ; but under the second licence they got for the first time what was called an "all-country" licence, which extended over the whole of the United Kingdom. Then they began to find out what telephony really meant, and what it was capable of. Licences were also granted to the Lancashire and Cheshire, and a number of other companies ; 13 licences in all being granted. On May 1, 1889, the United, the Lancashire and Cheshire, and the National Companies amalgamated under the name of the National Company ; then the Northern District Telephone Company, and the South of England Company came in, in 1890, followed by the Western Counties and South Wales Telephone Company, the Sheffield Telephone Company, the Caledonian Telephone Company, and others in 1892 and 1893. At the time of the agreement entered into between the National and the United Company and the Post Office, the two companies between them had practically the control of all the licences, with the exception of the Irish one. On May 1, 1890, the subscription in Manchester, Liverpool, and Warrington was £20 ; that was reduced to £15, and then on January 1, 1891, there was a general reduction of rates to a uniform charge of £10, which involved an immediate loss of revenue of £55,000 per annum on the then number of subscribers. When the amalgamation took place in 1889, the National Company had 10,813 subscribers, the United 6,793, and the Lancashire and Cheshire 6,230, making a total of 23,836 ; and by subsequent amalgamations and extensions of business, the number of subscribers had been increased to 73,353 for the year ending April, 1895. The number of towns and places supplied up to the same date was 537, the number of exchanges opened 593, the number of subscribers' lines 75,216, the number of telephones in use 86,032, and the present ratio of effective calls per annum 139,639,032, which was equivalent to, at the least, 279,278,064 messages. The annual average payment per line was £9. 2s. 2s., which gave an average cost to the subscribers per message of 0·58d. As 400 words could be easily spoken in three minutes, he estimated that the minimum number of words per message would be 100. Now, taking the average annual payment at £9. 2s. 2d., that works out to an average of 3s. 6d. per week, or 6d. per day, Sundays included ; every subscriber could, therefore, at his discretion, have the use of the telephone all the day, and in most places throughout the night, for the price of a sixpenny telegram ; and whereas 100 words by telegraph would cost 4s. 2d., the average cost per message by telephone was only a little more than a halfpenny. The number of messages had been estimated on accurate observations or accounts kept from time to time. It would be, of course, a waste of time and labour and expense to keep a daily record of every operator's business, and therefore they had to depend upon an estimate ; but the figures he had given were very carefully arrived at. When one could send a message by telephone at a cost of less than a penny, what became of the outcry about the extravagance of telephony ? Then a comparison had been made between the Company's charges and the charges made in other European countries. The figures he had already given did not encourage the complaint that the charge in England was an extravagant one, but if it were high the Company was not to blame for it. As he had said, the average annual charge per line was £9. 2s. 2d. Now what would that charge be on the assumption that the Company were relieved from those direct and extraneous charges not pressing, or very slightly pressing, upon State telephones in Stockholm, Berlin, Switzerland, and several other of the model examples ? There were in this country such things as royalties, wayleaves, rates and taxes, and then there were the greater relative scales of salaries, wages, and rents of premises. In the year ending December 31, 1894, the working expenses of the National Company amounted to £456,809. 15s. 4d., or 62 per cent. of the telephone revenue. The charges for royalty, wayleaves, rates and taxes amounted to £147,938, and the charges for salaries, &c., amounted to £214,123. The cost of line and instrument repairs came to £93,537, of which 72·89 per cent. represented wages. Now the wages paid in Great Britain to the people employed in that category were 33 per cent. higher than abroad, or a difference against the Company of £22,719. Then the salaries of officers, head office expenses and rents came to £120,586, which was at least 30 per cent. higher than similar charges abroad. That represented another extra cost against the Company of £36,160. The working expenses averaged £6. 4s. 7d. per line ; but if they were relieved of the burdens he had alluded to, the expenses would be reduced to £3. 8s. 4d. ; they would, therefore be lessened by £2. 16s. 3d., and if that amount were taken off the average annual charge per line of £9. 2s. 2d. the latter would then become £6. 5s. 11d. London made less use of the telephones than any other city in the world, when the number of its inhabitants was taken into account. He did not think the cause was to be found entirely in the cost of telephony ; it was rather to be found in the difference of circumstances. According to the tables which had been published by the German Postmaster-General, in Sweden 30·7 telegrams were sent annually by every 100 inhabitants ; in Germany it was 55 per 100 ; whilst in Great Britain it was 177·1 ; therefore, the telegraph was a much more severe competition here than abroad. The number of towns and places supplied with telephones in Germany

Digitized by Google

was 442, the number of telephones in use 91,458, the number of subscribers 84,129, and the number of messages 391,388,000. Then complaints had been made about the badness of the service, and the cost of establishing it. Well, they had had to train people to telephony just as in the early days of railways people had had to be trained to railway work. They had made mistakes, he admitted. He had no doubt that if they had all been wise—and it was easy to be wise after the event—they would probably have avoided the drawbacks of the single-wire system. It was an odd thing, however, that Berlin was absolutely single wire at the present moment. Unfortunately, in England they had started with the single wire, and no doubt that was the cause of a good deal of the discredit which attached to the Company. They were now doing their best to introduce the metallic circuit as rapidly as possible, although unfortunately the change could not be made without some disturbance and inconvenience to subscribers. The number of exchanges fitted or in process of fitting with complete metallic circuit wires and switchboards was 117, representing a total of 18,978 subscribers' lines. To show the increase in business, Witness mentioned that in Glasgow within the last five years the number of lines had increased from 2,652 to 5,292, in Edinburgh from 746 to 1,787, in Dundee from 837 to 1,309, and in Aberdeen from 584 to 1,063. Then as to the formal complaints which have been made by subscribers, the average number of complaints for the United Kingdom which have been received in the year 1894 was 0·73 per subscriber's line, the average number of exchange messages, local and trunk, per subscribers' line for the same year being 3,595. The average number of complaints in London was 0·94, in Manchester 1·56, in Liverpool 2·16, in Bradford 0·89, in Leeds 1·02, in Glasgow 3·79, in Edinburgh 0·09, in Dublin 1·30, in Belfast 0·47, and in Brighton 0·91. The witness then dealt with the foreign telephone tariffs. In Brussels the charge for a single wire was £10 within a radius of three kilometres of the exchange, £2 for each kilometre beyond this distance, and £1. 13s. 4d. for each extra kilometre; there was no royalty, and the number of subscribers was 2,400. In Amsterdam (which compared very well with London, because it was a financial, commercial, and social centre of great importance) the tariff was £9. 16s. 8d. for one kilometre; but in the suburbs the charge rose to £12. 10s., and in some cases £20. 16s. The free-speaking area in Amsterdam was about 30 square miles, and the number of subscribers 4,344. In Holland the telephone was in the hands of the State as a monopoly; the State erected the trunk wires, but they allowed the companies to work them, the companies handing over to the State 75 per cent. of the receipts for trunking. One peculiar thing about it was that although the State licensed the company to work, the company had also to obtain permission from the municipalities. The tariff for a three minutes' conversation in Amsterdam was a uniform charge of 10d., and the same sum was charged for every additional three minutes.

Mr. Forbes had not completed his evidence when the Committee rose. The Committee meet again to-day (Friday), when Mr. Forbes will be further examined.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May 10, 1895.*

Trolley Accidents in Brooklyn.—As the result of the numerous fatal accidents on Brooklyn trolley roads—there have been 109 up to date—public opinion has at last forced the city authorities to take decisive action. The president of the largest trolley road is now on trial for manslaughter; but it is thought there is little probability of conviction, this extreme measure having been resorted to in order to quiet public clamour. An ordinance limiting the speed of cars is having an amusing effect, the public loudly denouncing the astonished companies for the inconvenience they now suffer from the slow speed of the cars. It is quite probable that the railway officials are rather inclined, from ulterior motives, to keep well within the limits of the speed designated (eight miles per hour), but the service is yet immeasurably superior to what it was a few years ago, before the adoption of electric traction. The moral is that the public must have rapid transit, and that the many deaths resulting from this necessity are an unavoidable sacrifice to the exigencies of modern progress.

The New York Underground Electric Railway.—The Governor has just approved a Bill raising to $55,000,000 the limit of money that may be expended on the proposed underground rapid-transit system for New York City. Unfortunately, however, the period when construction will begin is quite distant, and some complication may yet occur to nullify the scheme. Much time will be required for condemnation proceedings, which will in turn give rise to suits attacking the constitutionality of the rapid transit law that will have to be finally decided in the Court of Appeals before construction work can be commenced. The law requires that the system shall not be built by the city, but by the successful bidder for the operating use of the road during a long term of years, the bid to be made upon a percentage of the cost of construction, the funds for the latter purpose to be furnished by the city. Thus far, there has been no indication of any bidder appearing when the city is prepared to receive offers; but an effort is being made to interest one of the Vanderbilt railroads in the matter. To this end the bait is held out that during the night hours two of the four tracks in the heavy shipping part of the city might be used for the direct transfer of freight cars to and from the premises of large shippers. While it has been decided to use electricity for the motive power, nothing has as yet been decided in regard to details, these being very wisely left to be taken up after the road is nearing completion, when full advantage of the latest improvements may be taken.

LEGAL INTELLIGENCE.

North Metropolitan Tramways Company v. London County Council.

This action was heard before Mr. Justice Romer, in the High Court, in order to raise the question whether the London County Council could, under section 43 of the Tramways Act, 1870, compulsorily purchase so much of the plaintiff Company's tramways and works and undertaking as are within the County of London, and as were authorised by the Company's special Act of 1871 without purchasing the whole of the Company's lines and undertaking. The arguments in the case have previously been referred to in *The Electrician.*

Mr. Justice ROMER, in giving judgment, said that on the main question the London County Council were right in their contention. In construing section 43 of the general Act of 1870, it was clear that the word "undertaking" was limited by reference to the tramway previously mentioned in the section, and was, no doubt, used instead of the word "tramway." It was noticeable that what was to be paid for was only the value of the tramway, and the lands, buildings, works, materials, and plant of the promoters suitable to and used by them for the purposes of their undertaking within the district. That being the true construction of the section, he could not see that there was any difficulty when the section had to be applied in the present case. The general Act of 1870 was incorporated, and under the powers of section 43 the London County Council are now entitled (the Board of Trade approving) to require the plaintiffs to sell their 1871 tramways, and their undertaking so far as it relates to those tramways. He did not see that this section was rendered inoperative or affected by the fact that the plaintiffs had other tramways, some of which were authorised by the prior special Acts of 1869 and 1870 respectively, and others of which had been authorised by later special Acts, or by the fact that their general undertaking related to those other tramways as well as to the 1871 tramways, and had from time to time, as further tramways had been authorised, been recognised and defined by the various special Acts as extending to and including the further tramways. The contention of the plaintiffs, if adopted, would lead to great difficulties. With regard to the argument founded on the inconvenience of the plaintiffs being obliged to sell their 1871 tramways only, leaving on their hands their other tramways, some of which could not be well worked efficiently or profitably by themselves, he did not think this contention of much weight, as any purchase by the Local Authority was subject to the approval of the Board of Trade, who would, no doubt, refuse their approval in a proper case. The plaintiffs, when they took powers to construct small pieces of tramway, did so at their own risk, well knowing the provisions of the general Act. Moreover, section 43 of the general Act expressly contemplated a tramway company being liable to sell portions only of its tramway, for if the tramway was in more than one district a Local Authority was entitled to buy so much only of the tramway as was in its district. For these reasons the plaintiffs' contention failed. The declaration as to the right to take the tramway would be that under the Act the London County Council were entitled to take the 1871 tramways, and also the plaintiffs' undertaking so far as it relates to those tramways.

Wood v. Woodhouse and Rawson United (Limited).

In a debenture-holder's action an application was made to Mr. Justice Vaughan Williams in the High Court on behalf of the Official Receiver and Liquidator of Woodhouse and Rawson United (Limited) for liberty to take proceedings against Directors of the Company in respect of alleged misfeasances.

Mr. H. WRIGHT, in support of the application, said that the Official Receiver estimated that there would be a deficiency of not less than £150,000, and it was extremely doubtful if anyone but the debenture-holders would be benefited by the proceedings against the Directors if they were successful.

His LORDSHIP said that if the unbiassed judgment of the debenture-holders was obtained and was against the misfeasance proceedings, his Lordship thought he ought not to allow the proceedings to be taken. He therefore thought it would be better to call the debenture-holders together, so that their views on the subject might be ascertained.

Digitized by Google

Mr. MACNAGHTEN, for the plaintiff, said that some disinterested person ought to be appointed to preside at the meeting, and he suggested that Mr. Leslie, of Coleman-street, E.C., the receiver in the action, should be appointed to preside.

His LORDSHIP said the Official Receiver must be appointed to preside. Although it might be thought improbable that anything would be obtained for the unsecured creditors, yet one could never be quite sure that this would be the result. If the debenture-holders arrived at a deliberate and honest conclusion that proceedings ought not to be taken, his Lordship would be very glad. But if their conclusion was based on the fact that they thought it a pity that there should be the scandal of subjecting respectable persons to proceedings, that ought not to be allowed to weigh much. Mr. Leslie must not suppose that because his Lordship had not appointed him to preside he had intended to cast the slightest reflection on him. His Lordship thought that under all the circumstances it would be better for the Official Receiver to preside. All the debenture-holders must be summoned to attend one meeting, but the voting must be arranged to take place in such a manner that it might be known how the persons belonging to the different classes of debentures had voted.

Bryson v. Cumming.

In the Court of Session, Edinburgh, before Lord Kyllachy, a settlement was announced in an action by Mr. W. A. Bryson, consulting electrical engineer, of Bothwell-street, Glasgow, against Sir William Gordon Cumming, of Altyre, Morayshire. Pursuer sued for £115. 18s. 5d. In March, 1892, he was consulted in connection with the fitting up of an installation of electric lighting at Altyre House, at an agreed commission of 4 per cent. on the cost of the installation, which was £3,063. Defender alleged that the pursuer had neglected his duties, and that he had been guilty of collusion with the contractors for the work.

By the settlement the defender has agreed to pay the pursuer £95 in full, and to withdraw all statements on record affecting the pursuer's professional character and reputation, each party to pay their own expenses.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price, 7s. 6d., post free 8s. 3d., abroad 9s.

The following New Books and Editions of "THE ELECTRICIAN" SERIES *can be obtained of the Booksellers or direct from the Publishing Offices*:—

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett. Strong portfolios can be had, price 1s. each. A full prospectus can be obtained post free.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

A LARGE-SHEET TABLE, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 3s. 6d.; Unvarnished, 3s. —each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell, with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

"ELECTRO-CHEMISTRY."—This useful work, by Dr. G. Gore, is still on sale, the price being 2s., post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"THE ELECTRICIAN."—A special notice concerning certain changes in the price, &c., of this journal will be found on page 124.

TENDERS INVITED.—The Electric Lighting Committee of the Huddersfield Town Council invite tenders for cables, transformers, switches, fuses, and covers for their electric lighting works during the ensuing 12 months. Specifications and particulars can be obtained of Mr. A. B. Mountain, borough electrical engineer, St. Andrew's-road, Huddersfield, and tenders have to be sent in to Mr. Mountain not later than Saturday, June 1st. Some particulars are given in our advertisement columns.

——— By command of the Postmaster-General, tenders are invited for the purchase of about 35 tons of old copper (wire, plates, &c.) and quantities of other metals, india-rubber covered wire, mercury deposit, india-rubber, tin foil, &c. Forms of tender can be obtained of Mr. Charles E. Stuart, Controller of Stores, General Post Office, Telegraph-street, E.C., and tenders must be sent in not later than 10 a.m. on Monday, June 17th. Some further particulars are given in our advertisement columns.

——— The Secretary of State for War gives notice that purchases of electrical instruments (submarine mining), telegraph cable and wire, india-rubber goods, &c., will be made during the current year, and manufacturers desirous of tendering should apply to Mr. G. Lawson, Director of Army Contracts, War Office, Pall Mall, London, S.W.

——— *Extension of Time.*—The time for sending in tenders for the supply of electric light lamp pillars and copper canopies required by the Corporation of Brighton has been extended until 10 a.m. of Saturday, June 1st.

——— The Shoreditch Vestry invite tenders for the wiring of the Town Hall, and for supplying and fixing cables, wires, switches, &c., for the electric lighting of the building. Tenders must be sent in to the Vestry Clerk, Dr. H. Mansfield Robinson, by the 31st inst. Our advertisement columns contain some further particulars.

——— The Corporation of Hanley invite tenders for the supply, delivery, and erection complete of boilers and fittings, water tank and girders, arc lamps, of cables, street boxes, &c., transformers, switches, &c. Tenders have to be in to Mr. Joseph Lobley, borough engineer and surveyor, before Monday next.

——— *Daily Tenders and Contracts* states the municipal authorities of Santos (Brazil) are inviting tenders for the supply of the requisite plant for lighting the district by electricity. Water power, which is plentiful near the city, is to be utilised.

——— The Electric Light Committee of the Oldham Corporation invite tenders for two 200-H.P. steam engines and dynamos and steam pipes. Tenders to be in by Tuesday next.

——— Tenders are being invited until June 29th by the Municipal Authorities of Braila, Roumania, for the concession for the lighting of the public streets either by electricity or gas.

——— The Manchester Corporation invite tenders for laying a system of underground telephone pipes, with inspection pits, service boxes, &c., in various streets of the city. Tenders have to be in by the 31st inst.

——— The French War Department, Paris, is inviting tenders until the 30th inst. for the supply of optical telegraphic apparatus required by the military telegraph service from the years 1895 to 1897 inclusive.

TENDERS ACCEPTED.—The Coventry and District Tramways Company have accepted the tender of Mr. C. Haywood, jun., for the erection of an electric generating station, car-sheds, &c.

——— The tender of Messrs. Babcock and Wilcox has been accepted for the supply and fitting up of boilers for the electrical department of the new post office, Leeds.

——— The Chelsea Vestry have accepted the tender of Mr. C. L. Hacking for the supply of electric light fittings for the upper hall of the Town Hall for the sum of £48.

——— The Halifax Board of Guardians have accepted the tender of Messrs. J. Sunderland and Co. for supplying and fixing electric bells at the new Vagrant Wards.

TENDERS RECEIVED.—The following tenders were received by the Brighton Corporation for the supply of vulcanised rubber and lead-covered and armoured cables. The quotations are per mile:—

	Two-core cable.	Three-core cable.
Siemens Bros. and Co. (accepted)	£239	£289
British Insulated Wire Company	215	230
Callender's Company	255	290
W. T. Glover and Co.	240	298
Fowler-Waring Cables Company	268	328
Telegraph Manufacturing Company	281	335
W. T. Henley's Telegraph Works Company	279	337
India Rubber Company	297	396

The Lighting Committee of the Town Council originally accepted the lowest tender of the British Insulated Wire Company; but as this was made in error, and the Company asked to be allowed to

Digitized by Google

withdraw, the offer of Messrs. Siemens Bros. and Co. has now been finally accepted.

Tenders Received.—The Brighton Corporation have also received the following tenders for the supply and erection of boilers at the Corporation electricity works :—

Babcock and Wilcox (Limited), London, accepted	£3,100
R. Taylor and Sons, Marsden	2,165
E. Danks, Oldbury	2,627
Fleming and Ferguson, Paisley	2,760
Spur, Inman and Co., Wakefield	2,870
J. Fraser and Son, Millwall	2,938
Tinkers (Limited), Hyde	3,060
R. Hornsby and Sons, Grantham	3,300
Fraser and Frazer, Bromley-by-Bow	3,486
Penman and Co., Glasgow	3,500
Davey, Paxman and Co., Colchester	3,644
J. Thompson, Wolverhampton	3,660
Hawkesly, Wild and Co., Sheffield	3,750
Yates and Thom, Blackburn	3,785
H. and T. Danks, Dudley	4,750

Sale by Auction.—On Wednesday next, at Wolverhampton, Messrs. T. J. Barnett and Sons will dispose of the extensive freehold property called Mitre Works, lately in the occupation of the Gospel Oak Iron Company (Limited), adjoining the Birmingham Canal, Bilston-road, Wolverhampton. The sale includes the freehold, covering an area of 3a. 1r. 1½p., with ranges of workshops, warehouses, stores, and offices, which have been specially arranged for the manufacture of galvanised wire, screws, &c. The plant and machinery, fixtures, tools, &c., are also to be disposed of.

Appointment.—The Electric Lighting Committee recommend that Mr. E. Sayer be appointed chief assistant electrical engineer to the Hampstead Vestry at a salary of £200 per annum.

Dissolution of Partnership.—Messrs. H. F. Jackson and T. A. Kerr, who have hitherto carried on business as electrical engineers, under the style of Whittaker and Co, at 85, Queen Victoria-street, London, E.C., have dissolved partnership. Debts by Mr. H. F. Jackson.

Bankruptcies.—The adjourned first meeting of creditors of J. Torr Todman, electrician, was held last week before Mr. A. H. Wildy, official receiver. There was no proposal before the meeting, but accounts had been filed showing gross liabilities £1,840. 10s. 2d., of which £725. 3s. 10d. was expected to rank, and assets £207. 7s. 2d. The debtor's solicitor stated that it was his client's intention to submit an offer of composition, and he applied for a further adjournment in order that an offer of at least 7s. 6d. in the £ might be made if the assistance which the debtor hoped for was forthcoming. Adjourned to June 14th, 11 a.m.

——— Messrs. L. P. Garrett and J. A. Rudd, Glasgow, and J. A. Buttery, Govan, have been appointed Commissioners in the sequestration of the estate of John Scott, sole partner in D. and G. Graham, electrical engineers, Glasgow. The examination of the bankrupt takes place at the County Buildings, Glasgow, on the 27th instant, at 11 a.m.

Liquidations.—A petition for the winding-up of the Madras Electric Tramways Company (Limited) has been presented by the Commercial and Land Mortgage Bank, and will be heard at the Royal Courts of Justice, Strand, London, W.C., on the 29th instant. Mr. Cyril Dodd, jun., 26, Bush-lane, London, E.C., is solicitor for the petitioners.

——— A petition for the winding-up of Ronald A. Scott (Limited) has been presented to the Middlesex County Court, at Brentford, by Messrs. Wells Bros., of Sandiacre, Nottingham, and will be heard on June 6th next. Messrs. Greene and Underhill, 31, Bedford-row, London, W.C., are solicitors for the petitioners.

——— It is probable that a meeting of debenture-holders in Woodhouse and Rawson United (Limited) will be called in a few days to discuss the question of the advisability of prosecuting the directors in respect of alleged misfeasance. The proceedings before Mr. Justice Vaughan Williams are briefly reported in another column.

——— A meeting is to be held at 9, Fenchurch-avenue, London, E.C., on June 19th, at 2 p.m., to receive an account of the winding-up of the European Sims-Edison Electrical Torpedo Company (Limited).

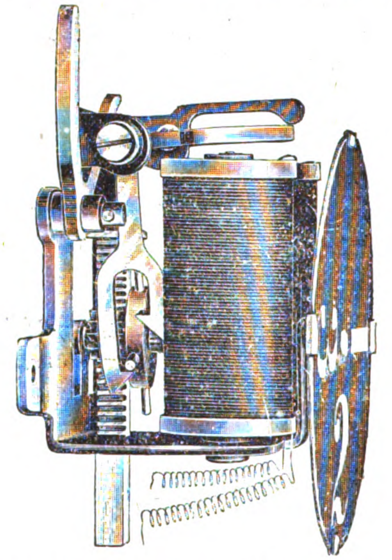
Mica Contract.—The Admiralty have placed with Mr. Archibald Campbell, of 28, Gray's Inn-road, London, W.C. (acting for Messrs. Baxters and Macdonald, of Dundee), a contract for mica.

Engineers' Tools.—Messrs. J. Carter, Sons and Co., of Salford, Manchester, have just issued a very complete catalogue of engineers', machinists', and general tools, consisting of lifting tackle, cranes, hoists, &c., and tools for engineers, machinists, &c., engine and boiler fittings, steam traps, pumps, injectors, &c. Nearly 90 large quarto pages are filled with illustrations and prices of an immense variety of engineering accessories.

Copyright in Designs.—Messrs. Sweet and Maxwell, of 3, Chancery-lane, London, W.C., send us a copy of "The Law of Copyright in Designs," by Lewis Edmonds, D.Sc., LL.B., Barrister-at-Law, assisted by Messrs. Stevens and Slade. The object of the authors is to present an exhaustive exposition of the English law of copyright in designs, which is a subject of great practical importance to manufacturing and industrial undertakings. It is pointed out that the number of designs annually registered is about 20,000. A very comprehensive "Table of Cases," and a simple index, making 21 pages, render the book of much service as a work of reference to those interested in the registration and copyright of designs.

"D.P." Batteries.—The D.P. Battery Company, Limited, of 66, Victoria-street, Westminster, S.W., have just issued Price List No. 1 of D.P. Batteries. The list is accompanied by testimonials from a number of users.

Triplex Movement.—The International Electric Company has recently patented and placed upon the market a new indicator movement, which allows of three signals being given with the same movement. It is constructed on the principle of this Company's universal bell, which was described in this journal some months back, and is intended to serve as a recording instrument where a pre-arranged code of signals provides for the using of the same bell to give different signals. The illustration gives some idea of



the arrangement of the triplex movement, and it is claimed that indicators fitted with this movement can be used with advantage on board ship, as it forms a perfect locking arrangement, only dropping when a current is past. An illustrated descriptive pamphlet can be obtained from the Company, 55, Redcross-street, London, E.C.

Electrical Heating and Cooking Apparatus.—The recent successful exhibition of electrical heating and cooking apparatus at the Portman Rooms, London, is a proof that the public are gradually according their appreciation to this branch of electrical industry. From Messrs. Crompton and Co.'s catalogue we take

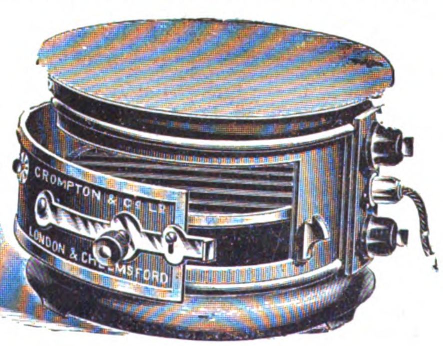


Fig. 1.

two of the most recent additions to the apparatus manufactured by that firm. Fig. 1 is a breakfast cooker, and combines an electric hot-plate and oven. Fig. 2 is an electric urn, and is used for heating water, milk, coffee, or tea. This article is made in a variety of shapes and patterns, and would be found of great service to restaurant keepers and others whose business premises are

Digitized by Google

situate in the area of supply of any of the electric supply companies. At present gas heaters are used, and the fumes of the gas-heated water boiler are usually very objectionable. In addition, the heat of the gas speedily burns off the outer polish, and, in fact, prevents any ornate treatment of the apparatus. With the electrical urn ornamentation can be indulged in to any extent, and for counter purposes this is a feature not to be altogether ignored. A useful heating device is shown in Fig. 3. This is for use in lavatories, and is intended for both hot and cold water supply.

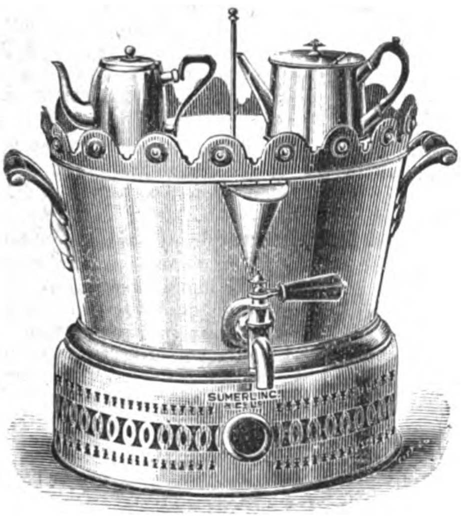

Fig. 2.

The cold water on entering the apparatus is electrically warmed in transit; the water can be heated to any temperature, and can be regulated by means of the dial shown on the right of the figure. If cold water is required, the pointer is turned from Z to K, and as the pointer is turned to the right so the water becomes hotter. The apparatus, which is manufactured by the Electrical Company (Limited), is claimed to be economical in use, and suitable for dealing with either large or small bodies of water.

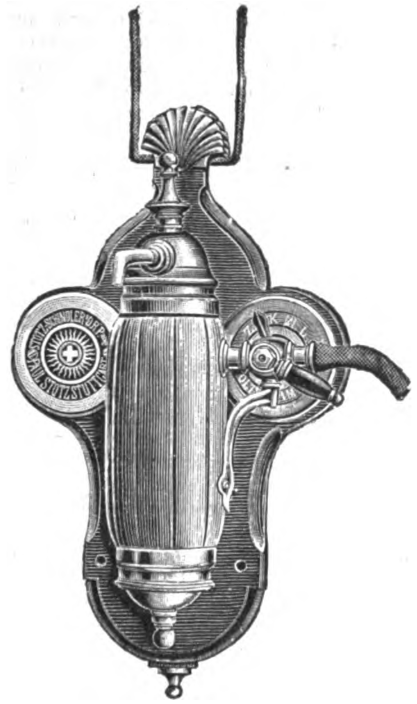

Fig. 3.

In purchasing electric heating and cooking apparatus it is most essential that the systems adopted by the makers for the actual heating arrangement should be carefully ascertained and examined. It is only by the adoption of a protective system, such as enamel or similar compound, that severe wear and tear of the conductors can be arrested. The pioneers in the manufacture of well-made electric cooking and heating apparatus may confidently look forward to reaping not only a full commercial reward for their exertions, but the thanks of a grateful public, for assuredly, if coal and gas cooking and heating can be satisfactorily and economically superseded by the more cleanly and easily-controlled electric method, the public will have reason to be grateful.

The Journal.—Part 117 of the *Journal* of the Institution of Electrical Engineers, containing Dr. N. S. Keith's Paper on "The Electrolysis of Gold," and the discussion thereupon, and also a Paper by Mr. W. E. Langdon "On the Employment of Electric Light for Railway Purposes," is now ready, price 4s.

Argentina.—It is stated the firm of Rufino Varela and Co. are drawing up the plans, &c., for lighting Bahia Blanca by electricity, and will shortly present a petition to the municipality asking for a concession for the public lighting.

Asylum Lighting.—The new Sunderland Borough Asylum at Ryhope, which was formally opened on the 16th inst., will be lighted throughout by electricity.

Birmingham.—It will be remembered that the contract for supplying electric light fittings and motive power for the Municipal Technical School, Birmingham, was some time ago awarded to Messrs. D. and G. Graham, of Glasgow. At the last meeting of the Town Council it was reported by the Technical School Committee that the trustee in the sequestration of the estate of D. and G. Graham (Mr. J. M. McLeod), in the exercise of the power conferred on him by his office, declined to fulfil the contract; consequently, the Committee recommended the acceptance of the tender of Messrs. B. Verity and Sons for the sum of £5,714. 11s. 11d., in place of that of Messrs. Graham. After a brief discussion the recommendation was adopted, a proposition to refer the matter back being lost. The amount of Messrs. Graham's tender was £5,515. 14s. 2d.

Bristol.—Mr. F. H. Tulloch, C.E., held a Local Government Board inquiry at the Council House, Bristol, yesterday (Thursday) respecting the application of the Corporation for sanction to borrow £10,000 for electric lighting extensions, and £32,048 for the erection of a refuse destructor, &c.——It is announced that the St. George and Kingswood Electric Tramway will be completed and running in July.

"Burglary."—The clerk Eve, who was charged with stealing £237. 10s. from the safe belonging to the Brush Electrical Engineering Company, was on Monday last sentenced to 18 months' hard labour. It was quite by chance that the prisoner was suspected, the robbery having been originally credited to burglars.

Cape Town and District Gas Light Company.—At a meeting of this Company last week, the Hon. H. Noel who presided, stated that although the electric light was established at Cape Town and the municipality was using it for street lighting in place of gas, as far as the gas company was concerned that would be a benefit to them rather than a loss, as the gas supplied for public lighting had been sold at cost price.

Cardiff.—The Corporation has been notified that the sanction of the Local Government Board to the application for powers to borrow £3,500, required for purchase of the site of the old brewery in Womanby-street, has been given. This is the site selected for an electric supply station.

Chiswick.—The lighting of this district, from reports to hand, leaves much to be desired. It is stated that those gas lamps which are not "out" give but a miserable glimmer of light, and this notwithstanding that the parish pays heavily under its lighting contract. The contract for electric lighting is in the hands of Messrs. Bourne and Grant, but the firm appears to experience much difficulty in its transactions with the District Council, whose latest order is that the erection of the shaft at the electric lighting station is to be stopped pending a satisfactory agreement being entered into with the Council. The prospect of an early turning on of the electric light, which we believe is much desired by the inhabitants, is likely to be considerably delayed, unless the authorities accept with a good grace the action of the previous District Council in handing over their Provisional Order to a company.

City Commission of Sewers.—At Tuesday's meeting of this body the Clerk presented an exhaustive report in connection with the circular-letter recently issued to telephone users. In all 3,456 circulars were issued and 1,085 replies received, which, seeing that the subject is supposed to be a burning one, does not appear a very complete return. This is, perhaps, accounted for by the fact that subscribers were somewhat embarassed by having no less than three separate circulars and three separate sets of questions to answer at the same time, and all in double-quick time. The opinion expressed in the majority of replies as to the inefficiency and costliness of the present service is stated to confirm the evidence given on behalf of the Commissioners to the Select Committee of the House of Commons now inquiring into the subject: 35 per cent. expressed satisfaction at the present service; 63·5 per cent. condemned the existing system as inefficient; 84 per cent. think the cost excessive; 10 per cent. do not object to the prevailing charges. The result of the canvass is to confirm

the Commissioners in their contention that a £10 subscription is considered as the limit of charge for subscribers within the metropolitan area.

COVENTRY.—At the meeting of the Town Council on Tuesday, on the recommendation of the General Works Committee, it was resolved to consent to the substitution of the Westinghouse system for the Thomson-Houston system in the equipment of the Coventry and District Electric Tramways. The Electric Lighting Committee reported that they expected to be able to supply electric current in August next.

"DANGERS OF THE ELECTRIC LIGHT."—When in doubt—try the electric light. A small outbreak of fire occurred at the residence of Mr. J. Garnet, at Bromley Cross, last week. The house is lighted electrically. In giving an account of the fire the newspapers naïvely state that "as there were only two fires burning in the house at the time, it is thought that the fire must have been occasioned by fusion of the electric light wires." Gas journals please copy.

DOVER.—A sensible suggestion has been made that Snargate-street, one of the principal thoroughfares of the town, should be lighted electrically by means of arches thrown across the street. It is a narrow thoroughfare, and this method of lighting would prove most effective. The memorial that the street should be lighted electrically has been signed by the whole of the occupiers.

EDINBURGH.—Messrs. Smith and Co. (Limited), electrical engineers, of George-street, have just completed the installation of the electric light in the Assembly Hall, which is the first of the large halls in this city to be lighted electrically.

EXHIBITION.—On May 13th the Mayor of Newcastle inaugurated a General Trades' Exhibition at Newcastle, which is to remain open till June 8th. Amongst the exhibitors are Messrs. Bland Bros. (electric light fittings and plant, telephones, &c.), Ackroyd and Best (miners' safety lamps and electric plant). Rowland Barnett and Co. (electric lighting plant, &c.), Robert Bowran and Co. (Blackman electric fans, "Sunbeam" incandescent lamps, &c.)

"EXPANSION OF TELEGRAMS."—Further interesting matter has appeared in *The Times* and the *Daily Chronicle* during this week on the subject of the charge made by the former journal against the Central News Agency of unduly expanding telegrams relating to the war between China and Japan. Mr. John Moore, manager of the Central News, writes that the remarks of the *Kobe Chronicle* are a "tissue of fabrications," to which the *Daily Chronicle* replies that the journal in question is a British paper, published in a British settlement, where full justice can be claimed by the Central News Agency if it choses to take legal proceedings. But *The Times* offers a much simpler way out of the difficulty. It offers to afford space for the publication of the original telegram of 204 words (expanded by the News Agency into 655), and considers this offer (and the public will endorse this view) is one which will enable the News Agency to justify its action, if possible. Further, *The Times* of Wednesday contained a request "that the manager of the Central News will kindly authorise the Eastern Telegraph Company to send to *The Times* for publication the '204 words in reference to Wei-hai-wei' received by the Central News on February 7th, as stated by their manager in his letter of May 14, 1895." To this request no reply has been vouchsafed. The *Daily Chronicle*, in its issue of Friday last week, brings what many will consider a still more serious charge against the Central News—of having sent out on April 30th a telegram which, "fortunately, most of the responsible London papers put in the waste-paper basket." The *Chronicle* describes this telegram as "a message which might conceivably have wrought much mischief if it had been believed on the Continent." The present silence of the Central News Agency is, perhaps, preliminary to its publishing a complete history of the whole transaction.

GLASGOW.—The balance-sheet of the first year's working of the Corporation Tramways is just issued, and is interesting from the fact that the successful working of tramways by the Municipality is assured. The period of working is ten months. The accounts show a balance profit of £13,743. Of this sum £7,496 is to be handed over to the Common Good Fund, and the remainder is set aside for depreciation. Electric lighting of the cars during the period has cost £128. 6s. 5d., and £466 has been spent in electric lighting plant.

KINGSTON-ON-THAMES.—At the last meeting of the Board of Guardians a letter from the Town Clerk was read suggesting the desirability of introducing the electric light into the workhouse. The Chairman said they had already decided that there should be electric light in the new infirmary, and it was agreed to wait until that installation was completed before they considered any extensions.

KNITTING BY ELECTRICITY.—The *Textile Mercury* contains an account, from an American source, of a machine now in operation which appears to offer a great improvement in the knitting art. It is described as an electrical attachment to a knitting machine, and is said to have attained such perfection that any design, however complicated, can be produced in the knitted fabric without preparatory operation or alteration upon any of the ordinary types of knitting machines, either straight or circular, thereby saving the delays of weeks, and in some cases months, that arise in setting up a pattern on the weaving loom. A pointed stylus is used, electrically charged, which successively follows the design over the whole surface of the metallic cylinder upon which the design is fixed. Any sized machine up to 9ft. in diameter, making a fabric of 17ft. wide, can be employed, and any number of colours up to 18 can be introduced into the design, according to the size of the machine. The inventor is Imanuel Buxtorf, a French mechanic and electrician.

LEEDS.—The Parliamentary Committee of this week discussed a communication from the Yorkshire House-to-House Company with reference to the Town Council's Tramways Bill, now before Parliament. The object the Company seek to attain is the extension in respect to the tramways it is intended to construct on the powers which the Company now possess in respect to existing lines. The Committee agreed to accept the proposal of the Company subject to some slight alterations which, if accepted, leaves the Tramways Bill without further outside, opposition.

LIBRARY LIGHTING.—The 137th annual general meeting of the proprietors of the Library, Liverpool, was held on Wednesday, and the president, Dr. W. Irvine, after dealing with the accounts of the undertaking, which appears to be in a very satisfactory financial condition, referred to the installation of the electric light, which the Committee of the Library report "as a very great improvement."

LONDON CHAMBER OF COMMERCE.—The thirteenth annual report of the Council of this Chamber is now ready.

OSSETT.—The Gas and Electric Lighting Committee of the Town Council recently passed resolutions regarding the price and quality of gas in the district, and have decided to make inquiries from neighbouring towns as to lighting arrangements, at the same time obtaining particulars regarding electric lighting.

PACIFIC CABLE.—A telegram from Ottawa, dated May 22nd, states that Fanning Island has been definitely settled as the Pacific Cable Company's station, which insures the route of the cable being entirely British.

PENISTONE (YORKS.)—At the last meeting of the Board of Guardians it was resolved to accept the offer of Messrs. Pettitt and Hards to send in specification and scheme for the lighting of the workhouse by electricity.

PROVISIONAL ORDERS.—The Electric Lighting Orders promoted by the Town Council of Stirling and the Town Council of Motherwell were unopposed before the Committee of the House of Commons, and were duly passed. The opposition threatened by the Caledonian Railway Company to the Order of the Motherwell Council was withdrawn.

RAILWAY STATION LIGHTING.—Messrs. Drake and Gorham have secured the contract for the lighting by electricity of the South-Eastern Railway Company's station at Tunbridge Wells, for which work, we understand, a number of tenders were submitted.

SOUTH AFRICA.—The success of the electric light and power plant supplied by Messrs. Siemens and Halske for the Rand Electric Company appears to be established. The *South African Mining Journal* says that small electric motors for underground haulage are shortly to be introduced, and promise to supplant animal traction.

WAKEFIELD.—The Electric Lighting Committee of the City Council recently decided that it was desirable that the proposed electric lighting works for supplying the city with electric current should be continuous to or combined with the buildings for the proposed sewage works. The Committee also decided that tenders for carrying out electric lighting work, at a cost of over £20,000, be advertised for, and the Council have approved the Committee's recommendation.

WALKER (NEAR NEWCASTLE).—At a meeting of the Tramways Committee of the Newcastle Corporation last week an offer was received from a firm of contractors to work an electric tram line from City-road to Walker boundary and then through Walker. Further consideration is to be given to the matter at the next meeting of the Committee, provided the consent of the Walker Local Board is given to the proposed scheme.

WEST HAM.—The Highways and Parks Committee of the Town Council recently presented a report on the question of lighting the borough by electricity. It is recommended that estimates be invited from some of the leading electrical firms for the installation of the light in the compulsory area, viz., High-street, Stratford, The Broadway, The Grove, Barking-road, and Victoria Dock-road. The report is to be considered by the Council in committee.

ROWING.—On Wednesday evening the members of a newly-formed rowing club (consisting of the staffs of the Eastern and associated Telegraph Companies) opened the season with a four-oared race on the Thames.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

April 18, 1895.

7,782. J. F. H. VOIGT and J. A. HAEFFNER. Liverpool. Improvements in electric resistances.

7,785. T. HARDEN. London. Improvements in connection with ventilating electric culverts, test-boxes, and other street-boxes.

7,788. W. R. RIDINGS, G. F. BULL, and L. B. CODD. London. Improvements relating to electric arc lamps.

7,795. VICOMTE G. DE S. DE DORMAEL. London. Improved construction of electrical accumulators.*

April 19, 1895.

7,829. W. J. S. BARBER-STARKEY. Manchester. Improvements in the method of and means for charging electric storage cells.

7,837. P. STOTZ and F. W. SCHINDLER-JENNY. London. An improved apparatus for electrically heating liquids.

7,888. E. ETEVE. London. Improvements in electric cells or batteries.

April 20 1895.

7,910. F. J. BORLAND. London. Improvements in and connected with apparatus for lighting up roundabouts and the like by electricity.

7,930. J. A. JECKELL. South Shields. Improvements in laying electric conductors underground.

April 22, 1895.

7,962. R. V. HOUSSART. London. An improved insulating compound.

7,966. W. E. DOW. London. Portable electric apparatus.

7,989. H. W. C. COX and GERSHON BOWMAR. London. Improvements in electrically-driven wool-shearing or hair-clipping machines.

7,990. F. H. W. HIGGINS. London. Improvements in telegraphy and apparatus therefor.

April 23, 1895.

8,011. G. HUBENER. Manchester. Improvements in the electrodes or plates of electric storage batteries.*

8,026. J. M. FAULKNER. London. Improvements in electric railway systems.*

8,037. A. MUIRHEAD. London. Improvements relating to electric telegraphs.

8,049. W. P. THOMPSON. Liverpool. Improvements in or relating to electric alarm clocks. (Rudolf Chillingworth, Germany.)*

8,072. E. WÜRL and A. NOWOTNY. London. Improvements in or relating to phonographs.

8,081. A. SCHANSCHIEFF. London. Improvements in the active material for secondary and primary batteries.

April 24, 1895.

8,135. F. HUGHES. London. An improved electric-light cask searcher and probe.

8,147. T. NEES. London. Combined trolley and accumulator system for driving electric cars.*

8,161. F. W. SCHINDLER. London. Improvements in electric igniting apparatus suitable for lighting tobacco pipes and cigars.

April 25, 1895.

8,167. A. LABRE and A. COUSSINET, Jun. Paris. System of electro-calorigen rheostatic chain.*

8,172. R. D. BAILEY. London. Belting for machine guns, dynamo, engine and other purposes.

8,186. A. HARVEY. Birmingham. Improvements in electric locks. (Samuel Bash: South America).

8,188. J. A. HIRST. London. Improvements in ceiling roses and lamp-holders for electric lighting.

8,195. O. HANKS. London. Improvements in cycle electric house table and other bells and gongs.

8,210. J. S. GISBORNE. London. A method of, and other means for, increasing the directive force of magnetic needles.

8,222. J. E. KINGSBURY. London. Improvements in telephonic systems and apparatus. (The Western Electric Company, United States.)

8,226. J. VON DE POPPENBURG. London. Improvements in and relating to electric batteries.

April 26, 1895.

8,253. T. COOPER. Walsall. Electric appliance to give signalmen control over drivers in foggy weather.

8,306. C. P. SHREWSBURY, F. L. MARSHALL, J. COOPER, and J. L. DOBELL. London. Improvements in or connected with electric batteries.

April 27, 1895.

8,373. W. S. RAWSON. London. Improvements in conductors for coupling cells of voltaic batteries.

8,392. M. MOSKOWITZ, L. D. ADLER, A. S. ADLER, and T. W. MYERS. London. An improved system of lighting and heating railway vehicles by electricity.*

8,393. M. MOSKOWITZ, L. D. ADLER, A. S. ADLER, and T. W. MYERS. London. Improvements in and relating to the electric lighting of railway vehicles.*

8,394. M. MOSKOWITZ, L. D. ADLER, A. S. ADLER, and T. W. MYERS. London. Improvements in means for equalising the electromotive force of dynamos.*

April 29, 1895.

8,398. A. S. F. ROBINSON. London. Improvements in the supporting and carrying of electric cables for conveying electricity over large areas, and to varying positions, whether for plough driving telegraphic, lighting, or other purposes.

8,421. R. FALSHAW. London. A new or improved automatic switch for electric welding and other purposes.

8,453. J. BROCKIE. London. Improvements in electrical switches, and means of actuating same.

April 30, 1895.

8,505. C. A. ALLISON. London. Improvements in the mode of and means for electrically transmitting articulate speech. (J. Absterdam, United States.)

8,507. J. A. JECKELL. South Shields. Improvements in disconnection fuse boxes.

8,537. A. J. BOULT. London. Improvements in insulating material. (The Virginia Phosphate and Paint Company, United States.)*

8,564. A. DUCEUX. London. Improvements in electric alarms.

8,573. W. S. SMITH and W. P. GRANVILLE. London. Improvements in electric cables and in their manufacture.

8,583. A. BERRY and J. LIPKOWSKI. London. Electro-automatic "block system" apparatus. [Date applied for under Patents, &c., Act, 1883, Sec. 103, October 30, 1894, being date of application in France.]

8,590. J. W. CARTER. London. Improvements in magnetic ore separators.

May 1, 1895.

8,603. H. REASON and G. W. GOLDRING. Brighton. Improvements in terminals for electrical conductors.

8,637. E. CLARK. London. Improvements in secondary batteries.

8,654. F. E. BEELTON. London. A rectifier for alternating electrical currents.

8,664. R. E. B. CROMPTON and E. A. N. POCHIN. London. Improvements in electric arc lamps.

May 2, 1895.

8,671. J. G. FIEGEHEN and E. G. FIEGEHEN. Bedford. Improvements in operating and controlling electrical and other cranes and hoisting machinery.

8,696. A. WRIGHT and R. C. QUIN. Brighton. Improvements in electric distribution and apparatus in connection therewith.

8,726. S. P. THOMPSON. London. Improvements in electric motors, generators, and current-converting apparatus.

8,727. SIEMENS BROTHERS AND CO. (LIMITED) and E. F. H. H. LAUCKERT, London. Improvements in switches for varying electrical resistance.

8,728. J. G. A. RHODIN. London. Improvements in plates for secondary voltaic batteries.

8,729. L. EPSTEIN. London. An improvement in secondary voltaic batteries.

8,731. J. BROCKIE. London. Improvements in electric arc lamps.

8,740. M. BAILEY and J. WARNER. London. Improvements in secondary batteries.

May 3, 1895.

8,764. A. WRIGHT. Brighton. Improvements in distribution of electricity.

8,810. SIEMENS BROTHERS AND CO. (LIMITED). London. Method of and apparatus for directly indicating the value of electrical resistances. (Messrs. Siemens and Halske, Germany).

8,834. O. LINDER and C. V. SWEEVELT. London. An improved system of electric traction.*

May 4, 1895.

8,884. H. J. HEINZE. London. Improvements in and relating to kinetographs, kinetoscopes, kineto-phonographs, kinetophones, and the like.

8,904. C. L. R. E. MENGES. London. Improvements in primary and secondary battery plates.

8,905. C. L. R. E. MENGES. London. Improvements in primary and secondary galvanic batteries.

8,914. A. R. DAVIS. London. Improvements in the preparation of chloride of lead for use in electrical storage batteries and for other purposes.

May 6, 1895.

8,966. H. A. ROWLAND. London. Improvements in meters for measuring currents of electricity, part of the invention being applicable to electric motors for driving astronomical clocks and other like apparatus.

8,967. A. GEUTZSCH and J. N. SCANAVI. London. Improved insulating material for cables and process of making same.*

8,972. W. LAWRENCE. New York. Improvements in electric railways.

8,994. W. JANDUS. London. Improvements in and connected with arc lamps.

May 7, 1895.

9,010. G. E. BAIRD. Manchester. Improvements in electric railways.

COMPANIES' MEETINGS AND REPORTS.

Western and Brazilian Telegraph Company (Limited).

The twenty-ninth ordinary general meeting of the Western and Brazilian Telegraph Company (Limited) was held yesterday (Thursday) at Winchester House, Old Broad-street, under the presidency of Mr. W. S. Andrews.

The SECRETARY (Mr. R. M. Cunningham) having read the notice calling the meeting and the minutes of the last meeting, which were approved by the present meeting and signed by the Chairman as correct, the report of the Directors was taken as read.

The CHAIRMAN: I see that we are honoured to-day by the presence of one of the gentler sex, so I must begin by saying—Lady and Gentlemen: The receipts last year amounted to £82,815, against £80,338, or an increase of £2,477. There is a small increase in the international words exchanged—words exchanged between Brazil and foreign countries—and there is a small decrease in the words exchanged within the territory of Brazil itself—that is, what we call internal words. The increase in the international words amounts to some 14 per cent., and the decrease in the internal words was something like 18 per cent.; but notwithstanding this decrease in the internal words exchanged, there is a small augmentation in the amount of the money derived from that traffic. That apparently contradictory, but, at the same time, satisfactory result, arises from the circumstance that the messages were conveyed on an average a greater distance than at the corresponding period, and therefore the product was a little more. There is nothing much to say with regard to the receipts beyond what I have stated. The expenses for last half-year were £36,403, against £35,592, or an increase of £811. As you know, we usually take abstract A and go through it item by item, but in this case two items cover more than the total increase—namely, wages abroad, £789, and maintenance, £353, which would land us already in upwards of £1,000 increase; but as against this increase there are items of decrease—namely, medical, rent, furniture and stationery, aggregating some £400, and therefore reducing the total increase to £995. Under abstract B—ships—there is an apparent total increase of £44; but the expenses under ships are rather larger than they would normally be owing to exceptional and, as we hope, non-recurrent causes. Of course, it would not be worth while to take up your time and practically waste it by talking about an increase of £44; but we take a strong interest in our shipping. We work at it always with the idea of reducing its expense as soon as we can, and therefore we are going to tell you one or two facts as regards the shipping which will no doubt be satisfactory. In truth, the permanent charges of the ships have undergone diminution. For instance, this half-year the ship was 564 more hours at sea, or an increase of 34 per cent. on the work which she had to do in her absence from port. Of course, this additional steaming and working involved a larger expenditure on account of coals, footing up some 873 solid

Digitized by Google

sovereigns. Then, another circumstance came into play—namely, that we lost largely in our rebate upon insurance—in other words, if the ships remain in port for a considerable period, we get a rebate on the insurance money we pay. On this occasion, however, the ship was not in port. The ship was at sea, and consequently we found ourselves at sea in this respect—that we could not claim this rebate, and that makes another £441. Altogether, we hope that this increase together of about £1,314 may be exceptional, but we cannot say that it will be, as we may have another bad year. The increase on this occasion was of course owing to natural causes, and therefore causes which are non-controllable. Another incident arose which I must not go into too closely ; but owing to political circumstances we lost the services of an old captain, who was a very able and zealous, and at the same time a skilful officer, who rendered very good work to the Company over a large number of years. This landed us in certain compensation, travelling expenses, and other outlays, which we may deal with, atall events, as an absolutely non-recurrent item of over £700. Therefore, but for bad luck with respect to breaks and the other causes I have mentioned, we should not be £44 to the bad, insignificant as that sum is, but over £2,000 to the good, under abstract B. In other words, you see that our arrangements would have resulted in a further saving, which would have compared very favourably with the corresponding period, but for the facts I have just enumerated. Under abstract C there are four items of increase—rent, stationery, law charges, and so on, with respect to which, by-the-bye, some part will come back, as we have won the case in which they were mainly incurred. There is some increase in furniture, but there are five items of decrease, salaries and wages, office expenses, stationery, freight, and life insurance. The total increase under abstract C, allowing for the decreases, is £227, and I do not propose to labour that. There is one thing with respect to the ships which I desire to mention. We have not thought it wise to write down these ships or to interfere with them. They are laid up, as you know, at the smallest cost. One of them is ready for sea if we can get a charter for her at any moment. As our accounts have gone out to Brazil we thought that any alteration in them would really only complicate and disturb matters, and therefore it was better on all grounds to leave the ships exactly on the same basis as they would appear in what had already gone out to the Brazilian Government. In fact, it was important to preserve the *status quo*, and we think we were right in doing it as far as we could. The outcome of all the figures is that, after deducting debenture interest, £11,601, and placing £5,000 to the debenture redemption, there remains £40,059, from which £8,000 has been placed to the reserve, leaving £32,059 to be dealt with as the net profit of the six months. The Directors are enabled to recommend a dividend of 6s. per share, free of income-tax, which makes, with the dividend paid in November, 3 per cent. for the year. This compares with 2½ per cent. for the year 1893, and leaves a respectable balance of £2,846 to be carried forward to 1895. Considering the loss sustained on exchange by the Western and Brazilian Company and the Platino Company of £19,960 and £11,414—together no less than the very considerable sum of £31,374 for the half-year—we think this result is not unsatisfactory. The fact is, gentlemen, that, as you have been told before, this Company ought to be in a position to satisfy everyone who has invested in it. If only the exchange came right that would be the case. I need not go into the figure of that large sum of money, as you will see that it would give you a very satisfactory increase to your dividend. The one item of exchange, in fact, is the governing factor in your affairs. With a satisfactory exchange the Company would be enabled to give a very gratifying account of its operations. We can only hope that affairs in Brazil will become still more tranquil, and that the commercial activity of the country will increase, as well as its security generally, so that men can get about their work without disturbance. No doubt exchange would then improve, as well as all the surrounding circumstances, and whether we were bought up by the Government, or were not bought up, I should look at the future through not unsanguine spectacles. The next question I have to deal with is that of the action which we reluctantly had to bring against our friends the Brazilian Submarine Company with respect to our claim of some £6,000 a year, and with respect also to a question of considerably more importance than £6,000 a year to us—namely, the question of the control of the tariff, which the Brazilian Submarine Company at that time claimed That was fully gone into at the time. I gave you all the particulars about it, and I daresay you will not want to hear anything more about it, especially when I tell you that the whole of the questions raised have been decided in your favour, with costs. That removes a great source of trouble which we had with our friends, the Brazilian Submarine Company, because we are friends. We are closely allied. We could agree to differ without any display of temper, and the questions raised I have no doubt were raised on the other side conscientiously, and without any desire to take advantage of us in any way ; but, at all events, the result has proved that we were right. No doubt the shareholders remember that we undertook certain obligations—some shares and so on—to secure the establishment of a Pacific and European Telegraph Company. That Company gave us direct telegraphic access to the West Coast of America. Unless we had undertaken certain obligations we should not have succeeded in establishing that undertaking ; but it has now been established, the connection has been made between Buenos Ayres, and Valparaiso, and I am pleased to say that the traffic which this operation has brought to the Company's line has been satisfactory. It continues daily to develop, and wears a very encouraging appearance. You see by the accounts that we take credit for £5,000 as the revenue derived from this traffic during the period the line has been opened. That £5,000 is an estimated figure, and perhaps it is therefore necessary to say that, although it is an estimated figure, it cannot be reduced. The line was actually opened on March 18, 1894. At first the receipts were comparatively small, but the business went on increasing, and I have to congratulate you upon what I believe will turn out to be a decidedly valuable addition to the system of the Company. Now, up to this point, I have been dealing with the business of the concern upon the basis that it is a continuing one, but all of you know that the Government has given the Company notice to acquire the lines under the original concession. The matter was fully gone into at the last meeting, when I think that every explanation was given upon it that could be given, and the shareholders know practically as much as we do with respect to the position. There is, however, certainly a change in the position. At that time, if you remember, I dealt with the whole thing as a mere project. It was talked about, suggested,and there was an idea that an offer would be made,but the Government had no power, and it was a good deal in the clouds. It required to become law that the Government should be fully empowered to proceed further. In pursuance of the intentions of the Government, which evidently have been serious all the way through, application was made for the necessary authority to the legislature of the country, and the latter, after having given full consideration to the case, has passed an Act, which has been duly signed by the President, and it is now the law of the country. Therefore the scheme, or whatever it may be termed, has passed out of the region of projects, and the power to acquire the concern has become part of the law of the United States of Brazil. I did intend to read that paragraph in the report headed "Acts of the Legislative Power," but it is hardly worth while, because you have all had it, and know as much as I do about it. At all events, as you see, a step further, and a valuable step, has been taken, for the Government has actually acquired full authority from the legislature to purchase the undertaking, and, therefore, the negotiations and the arbitration will be in good time begun in Brazil, and we shall here have to await the outcome of that, whatever that outcome may be, with what patience we may. You know that as a rule governments do not move with lightning speed, even in the ordinary affairs which come before them. Matters are generally considered very deliberately, and are not hurried, and it is not likely, I think—this is a matter of personal opinion—that a question of this great magnitude will prove an exception to the rule. What we have done, of course, has been to take into counsel the best expert opinions we could get. We have had the case thoroughly examined. We have had reports from people competent to give them upon the value to be attached to the property, and indeed the case has been thoroughly and exhaustively examined from every point of view. We do hope and trust that these exertions of ours and others, and the careful examination that has been given to the case, may not prove unavailing when the time comes for consideration, discussion, and settlement. I do not think I need trouble this meeting any further, but after putting the motion for the adoption of the report I will await any observation which may be made. At the same time, if you will allow me, I would venture to suggest that we are still in the stage of negotiation—almost incipient negotiation—and remarks directed to the purchase question are, perhaps, a little to be deprecated. I now beg to move—

"That the report and accounts to December 31, 1894, be and are hereby approved and adopted, and that a dividend of 6s. per share, free of income-tax, making, with the interim dividend paid in November last, £3 per cent. for the year 1894, be and is hereby declared payable on the 24th inst."

Mr. C. W. EARLE seconded the motion.

The CHAIRMAN : The resolution has been moved and seconded, but before I put it to the meeting I will take my seat, in order to listen if you have any observation to make or question to put. After a pause, and no shareholder rising to speak, he continued : Gentlemen, I am very pleased to gather from the silence which prevails at the meeting that the Board have the confidence of the shareholders, and they have always tried steadily to gain it and to keep it. He then put the motion in the usual way, and, having declared it carried unanimously, said: It is now my duty to retire from this dignified position, and one of the Directors will take it for me.

Mr. EARLE then took the chair, and proposed the re-election as a Director of Mr. Andrews. The shareholders had, he remarked, so often heard Andrews' very clear and business-like statements at their meetings that he (the speaker) need not say a word respecting their Chairman's ability. When, too, it was remembered that Mr. Andrews was perhaps the most experienced gentleman in existence in the administration of telegraph companies, having been connected with them almost all his life with great success, he thought that there would be no opposition to the resolution.

Lord RICHARD H. BROWNE seconded the motion, which was carried unanimously.

The CHAIRMAN then resumed his former seat, and after thanking the shareholders for re-electing him, proposed the re-appointment of Mr. D. H. Goodsall.

Mr. JOHN COPPEN seconded the motion, which was carried unanimously.

A discussion then arose as to the re-appointment of auditors. For many years Messrs. Turquand, Youngs, Bishop and Clarke were the auditors to the Company. A short time back Messrs. Deloitte, Dever, Griffiths and Co. were appointed to act with Messrs Turquands. These firms jointly pointed out that the rate of remuneration for the Company's audit was inadequate, and Messrs. Deloitte offered to resign in favour of Messrs. Turquands, the original auditors for the Company. This offer was accepted, Messrs. Deloitte being thanked for their efficient services. Finally Messrs. Turquands were appointed auditors to the Company at a remuneration of 100 guineas per annum.

Major COTTON proposed a vote of thanks to the Chairman for his conduct in the chair, to the Directors, and to the Managing Director, Secretary, and staff for their services in the past half-year.

Mr. FROST seconded the motion, which was carried unanimously.

The CHAIRMAN returned thanks on behalf of the Directors and the officers, and the proceedings then terminated.

West India and Panama Telegraph Company (Limited).

The thirty-sixth ordinary general meeting of the members of this Company was held at Winchester House, Old Broad-street, on Wednesday, Mr. C. W. Earle in the chair.

The SECRETARY (Mr. R. T. Brown) read the notice calling the meeting and the minutes of the last meeting, and the report of the Directors was taken as read.

The CHAIRMAN: I am sorry to say that the report is the least satisfactory in its results of any that we have had to make to you since 1882, and I do not know to which side of this table more sympathy is due —whether to us or you—to you for the long-continued self-denial displayed by you in restoring this Company to the position of credit it now enjoys, or to ourselves, who are disheartened by finding the poor dividend we have been in the habit of giving you vanishing, and that all the labour and all the thought that have been devoted to making this service a really good and substantial one have been almost fruitless as regards the ordinary shareholders. The only consolation that we have is that the causes of this unfortunate position of things are entirely beyond our control. At our last meeting I alluded to one or two of these causes—principally the decline of business in the West Indies and the decline in the value of sugar, which really seems to guide our receipts. When sugar goes up we get more traffic; when it goes down, as it has done persistently for a great many years now, there is a decline. The other day there was a little spurt in sugar, and you might have seen by the returns that there was at once an improvement in the traffic. Another influence which I referred to was the increase in the skill of using the codes by the merchants. That skill has gone on slightly increasing during the year 1894. In 1869, when this Company was first started, and obtained its Acts from the Colonial Governments, it was laid down in the rules for the tariffs that the minimum message should be 20 words, and it was only in deference to the growing custom among telegraph companies all over the world that we introduced the word rate some 18 years ago. By the introduction of that word rate the merchant, instead of having to send and pay for 20 words, now forwards an average message of about 7·25 words, showing what an immense advantage, in comparison with the original conceptions of this undertaking, the merchants in the West Indies are gaining. The decline in the traffic amounts, as the report states, to about £2,000, in comparison with that of the corresponding period of the previous year, and there has not been a single station cut off during the whole of the half-year under review. The whole of that loss was therefore attributable to the decline of business in the West Indies. Looking to our accounts, there is not, as usual, very much to remark on the expenditure side. There are slight variations in some of the items, but I hardly think it is worth while taking up your time by referring to them. They are very small. In abstract A there is an increase in the expenses, owing to the variations in some of the salaries, of £40; and in abstract B there is an increase of £45 from the same cause. The whole of the expenditure is £1,011 more than it was in the corresponding period of the previous year, of which £952 is due to the items under abstract C. These are influenced by circumstances over which we have not the slightest control. The winds and waves in the West India seas have not this half-year been very much "tempered to the shorn lamb" of our Company. Looking at the credit side of the revenue account, we have received £1,022 less than in the December half of 1893; and to sum up the result of all these variations, we find that, with £1,022 less receipts and £1,011 more expenses, we have less by £2,033 than in the corresponding period of the previous year. If we had had that £2,033 we should, of course, have been able to pay you a dividend of 6d. on the Ordinary shares. I daresay you would like to hear something about the prospects of the current half-year. Well, the traffics are slightly diminished, but very slightly. The expenditure on the cables will not, I hope, be very great. At the same time, as we announce in the report, we lose the £2,000 a year hitherto paid us by the Island of Guadeloupe. Our prospects, therefore, are not, on the whole, very bright. It is rather curious that while this diminution of revenue is going on, and the difficulties we are going through, are apparent to everyone, meetings are being held in the principal Colonies of the West Indies, who are passing resolutions calling on their Governors to put pressure on the Secretary to the Colonies to subsidise, at the cost of the English taxpayer, a single line of cable running to the middle of our system, and to reduce the rate to about 3s. per word to the West Indies. I do not know whether there is much chance of these proposals being adopted by the Secretary to the Colonies, or whether Parliament will grant him a subsidy to relieve the West India merchant from the expenses of his business; but when one remembers that our system was duplicated by the pressure, the entreaties—I might almost say the threats—of these West India Colonies, to give them a reliable system without interruption—which no single cable can give—it does seem to me rather hard that they should agitate now for a single cable. A single cable, as long as it is working, can work for much less than a duplicate system, because the capital, mile per mile, is only half, especially in a system like ours, where the traffic does not occupy the cables except for part of the day, they remaining idle for the rest of the 24 hours. I do not fear that this movement will have much effect here; but we must always be prepared for some surprise of this sort. One of the reasons advanced for this measure is to have cables passing through exclusively British possessions. It is supposed that in a great war these cables which only land on British Colonies will be free from the attacks of the Power we are at war with. It is only in the event of a great naval war that these tactical cables would be of any special use; but I say that directly we have a great war all cables will be torn up by the enemy. Is it likely, if we were at war with France—which heaven forbid!—France would allow us to have our cables working peacefully, when a harbour tug could go and pull them to pieces in a night? It would, therefore, be waste of the taxpayers' money to subsidise a tactical cable where you have our commercial cables doing the work already. If any of you have any questions to ask I shall be very happy to do my best to answer them. I now propose—

"That the Directors' report and accounts to December 31, 1894, submitted to this meeting be, and the same are hereby received and adopted, and that, as recommended by the Board, dividends of 6s. per share on the First Preference shares, and 6s. per share on the Second Preference shares be and the same are hereby declared."

Mr. WILLIAM ANDREWS seconded the motion.

Mr. DYETT asked whether there was any chance of any reduction in the expenses and in the Directors' fees, as he saw no other hope of the Ordinary shareholders receiving anything.

Mr. W. GRIFFITH said that they must agree that the report was not very exhilarating. Circumstances had been against them, and it was difficult to see what could be done in the future. A reduction of expenses would produce a little, but he thought that they had an equitable claim on the Governments of the Colonies, which the latter did not consider. The Company gave them a very useful service and provided them with news, for which they got only a wretched return. They might not be able to compete with foreign Governments, but at the same time it was possible that the cable of a private company did its business better than a cable which was under the control of the French Government. He agreed with the statement in the report that "the duty of maintaining an efficient service, and of fulfilling the unprecedented obligation of providing news to the Colonies is one that, in existing conditions, it is impossible to perform." The only thing they could do at the present moment was to rest on their oars. They ought not to be very prompt in spending money in making repairs or in providing news. If they could reduce their expenses in this way the Colonies would have to thank themselves for the less efficient service received by them. The Company had done their duty, but had not been paid for it, and the Colonies must put up with any inconvenience which might arise from a more dilatory service.

The CHAIRMAN said he did not see his way to reducing the expenses further, for they were already reduced to as low a point as possible. He would not say all that he knew might happen in connection with Mr. Griffith's recommendations. The first thing would be the stoppage of their subsidies, which would put them in a worse position than they were in at present. He did not think there was any other course but to go on maintaining the service. If they were not to repair their cables when they were broken they would be practically leaving the thing to be picked up by other people. He did not for his own part see that there was any solution of their difficulties in Mr. Griffith's advice. To refuse to spend any more money on the concern would be to destroy the foundation of the whole enterprise, and he did not think they would get anything out of it. With regard to the remarks about the Directors' fees, if any one would take his place he would be glad to give his successor his salary.

Mr. DYETT stated that in abstract A the item of salaries appeared as £1,040, while in abstract B there was an item of "salaries and wages" £6,154. These sums amounted to £7,000 odd, which was a good deal.

The CHAIRMAN stated that abstract A referred to London and abstract B to the 21 stations abroad; and having skilled operators in the tropics was expensive. He ventured to say that there was no telegraph company which so closely watched its expenditure as this Company did.

Mr. GRIFFITH desired to state that he had not proposed the extreme course of not repairing their cables at all; he had suggested that they should take their time about it. There were two steamers, and one was sufficient to effect all their repairs.

The CHAIRMAN remarked that that was fortunately the case last half-year.

Mr. GRIFFITH desired to know whether they could get rid of one steamer, by which, he said, a large amount would be saved.

The CHAIRMAN replied that the second steamer, "Duchess of Marlborough," cost the Company only about £400 a year, as she is lying up in dock in London, instead of about £7,000 a year when in commission. They had thought about this matter fully, and they must have a second steamer in port ready to proceed abroad on the return home of the other steamer. Unless they were in a position to repair their cables when they broke the subsidies would stop. In further reply to Mr. Douglas J. Patterson and Mr. Richardson, who also criticised the expenses, and suggested the retention of one steamer only, the Chairman stated that the main object of the reserve fund was to meet repairs and renewals. The reserve fund was calculated upon the basis of the "life" of a cable, which they estimated at 30 years; and if they dipped into this reserve now for their repairs they would leave themselves without a reserve at all when the cables had to be renewed throughout. He quite sympathised with the position of the Ordinary shareholders. The idea that they had a vessel which was kept as a pleasure yacht was an absolute delusion. The "Duchess of Marlborough" was available in case of any great disaster to their cables requiring the services of two ships, or whenever the other ship had to come home.

Mr. JOHN NEWTON agreed that the Ordinary shareholders' case was very much to be pitied, but it was the Ordinary shareholders' lot to have to bear the brunt of the misfortunes of a company. In the early days of this Company the shareholders were asked to provide Preference capital on certain conditions, and they did so. For the past 20 years the Directors had had the care of the Company, and they had brought it from a worse position than it was in now, for a sufficient reserve fund had been formed for preserving the *corpus* of the Company. Without the reserve fund the Ordinary shares would not be worth 1s. in the market, and the Preference shares would be quoted at a considerable discount also. He was convinced that the greatest economy had been practised by the Directors, and the Ordinary shareholders could not mend their position by reducing the

Digitized by Google

remuneration of the Directors upon present circumstances. He also thought that the question of whether one or two cable repairing ships should be kept was purely one of administration; and the Directors must know best what was necessary for protecting the Company. They must protect their Debenture and Preference capital, or their undertaking would be nowhere.

Mr. PATTERSON: The debenture holders and the First and Second Preference shareholders are very well cared for.

Mr. NEWTON: That is exactly why they subscribed their money. Unless they had that protection they would not have subscribed at all.

Mr. CHAMBERLAIN said he would be very glad to have a dividend on his Ordinary shares, but he would be extremely sorry if the Directors were to tamper with the reserve fund in order to declare a dividend for a single year.

The CHAIRMAN repeated that the Directors had come to the decision that it was advisable for them to have a second ship, for the reasons he had already stated. If anything happened to the ship that was away and they had not a second ship to send out to replace her, they would have to charter a vessel so as to keep up the system and maintain their revenue. He then put the motion, and declared it carried with five dissentients. Resolutions were afterwards passed re-electing Mr. Henry Holmes to his seat at the Board and reappointing the auditors, Messrs. Deloitte, Dever, Griffiths and Co.

Mr. CHAMBERLAIN then proposed a vote of thanks to the Chairman and Directors. It was, he said, very unpleasant to have money invested and to receive no return on it, but it was extremely hard also for those who had the conduct of affairs—the Directors—to feel that things were beyond their control, and that it was perfectly impossible to get in a revenue which would enable them to declare a dividend.

Mr. JOHN NEWTON seconded the motion, and expressed his belief that the Directors had done all they could.

The resolution was agreed to.

The CHAIRMAN briefly acknowledged the vote, and the proceedings then terminated.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1895, pages *304-332, &c. &c.*]

HARRINGTON ELECTRIC LIGHT COMPANY (LIMITED).—This Company was registered on May 18th, with a capital of £3,000, in £1 shares, to carry into effect an agreement made between W. A. Whiteley and George Fletcher, of Long Eaton, Derbyshire, to carry on the business of an electric light company in all its branches, to construct, lay down, establish, fix cables, wires, lines, accumulators, lamps and works necessary for the same; and to carry on the business of electricians, mechanical and electrical engineers, suppliers of electricity for the purposes of light, heat, motive power, or otherwise, and manufacturers of and dealers in electrical apparatus of all descriptions. The first Directors are:—T. Pegg, W. Thurman, E. Dalby, G. Fletcher, and W. A. Whiteley.

BRITISH ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company to December 31st has been filed; 8,641 shares have been taken up out of a capital of £100,000, in £10 shares, and 1,145 have been issued as fully paid. The full amount has been called and paid on the remaining 7,496 shares.

BRITISH INSULATED WIRE COMPANY (LIMITED).—The annual return of this Company to March 27th has just been filed. The nominal capital is £110,000, divided into 300 Founders', 3,950 Preference, 9,450 Ordinary "A," and 8,300 Ordinary "B" shares of £5 each; 298 Founders', 3,720 Preference, 6,962 Ordinary "A" and 8,053 Ordinary "B" shares have been taken up, of which 219 Founders', 975 Preference, 575 Ordinary "A" and all the Ordinary "B" shares have been issued as fully paid. The full amount has been called on the remaining 79 Founders', 2,745 Preference, and 6,377 Ordinary "A" shares, and £46,270 has been paid.

CHAMBERLAIN AND HOOKHAM (LIMITED).—The annual return of this Company to April 17th has been filed; 1,000 "A" and 5,000 "B" shares have been taken up out of a capital of £100,000, in equal numbers of "A" and "B" shares of £10 each, and the "B" shares have been considered as fully paid; £3. 10s. per share has been paid on the "A" shares.

CHELSEA ELECTRICITY SUPPLY COMPANY (LIMITED).—The annual return of this Company, to March 19th, has been filed. The nominal capital is £100,500, divided into 14,000 Ordinary and 6,000 Preference shares of £5 each, and 500 Founders' shares of £1 each; 10,277 Ordinary, all the Preference, and all the Founders' shares have been taken up; 6,666 of the Ordinary and the Founders' shares have been issued as fully paid. The full amount has been called on the Preference and the remaining 3,611 Ordinary shares, resulting in the payment of £48,055.

COLLIER-MARR TELEPHONE AND ELECTRICAL MANUFACTURING COMPANY (LIMITED).—The annual return of this Company to January 17th has been filed. The nominal capital is £100,000, in £10 shares, and 4,592 of these have been issued as fully paid. In addition, 935 have been subscribed for and allotted, and the full amount has been called, resulting in the receipt of £9,155. £175 has been paid in respect of 88 forfeited shares.

CORLETT ELECTRICAL ENGINEERING COMPANY (LIMITED).—The annual return of this Company to May 13th has been filed. Out of a nominal capital of £10,000, in £10 shares, 620 have been taken up. 100 of these have been issued as fully paid, and the full amount has been called and paid on the remaining 520 shares.

CROMPTON ELECTRIC SUPPLY COMPANY OF AUSTRALIA (LIMITED).—The annual return of this Company to February 7th has been filed. The nominal capital of £50,000 is divided into 9,500 "A" and 500 "B" shares of £5 each; 3,115 "A" and all the "B" shares have been taken up, and the latter have been issued as fully paid. The full amount has been called on the "A" shares.

CROMPTON-HOWELL ELECTRICAL STORAGE COMPANY (LIMITED).—The annual return of this Company to May 10th has been filed. The nominal capital is £19,600, divided into 19,000 Ordinary shares of £1 each, and six Founders' shares of £100 each; 12,007 of the Ordinary and all the Founders' shares have been taken up and the latter have been issued as fully paid, while 8,000 Ordinary shares are considered as having 15s. per share paid; 16s. per share has been called on 4,007 Ordinary, and 1s. per share on 8,000 Ordinary, resulting in the receipt of £3,605.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The annual return of this Company to April 12th has been filed. The nominal capital is £95,000, divided into 13,000 Ordinary and 6,000 Preference shares of £5 each; 12,931 of the former and all of the latter have been subscribed for and allotted, and the full amount is called.

DOMINION ELECTRICAL COMPANY (LIMITED).—Mr. H. F. Jackson, electrician, who was the largest shareholder in this Company, has asked that the name of the concern may be struck off the register, as it is now doing no business.

CITY NOTES.

BLAKE AND KNOWLES STEAM PUMP WORKS (LIMITED).—Notice is given of the drawing of 100 debentures of £100 each of this Company, which will be repaid on or after July 1st next, together with interest up to that date, either at the offices of the Trustees, Executors, and Securities Insurance Corporation (Limited), Winchester House, Old Broad-street, E.C., or at the Company's head offices, 95, Liberty-street, New York.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended May 19th were £905, as against £907 in the corresponding period of 1894, being a decrease of £2. The total receipts for the half-year amount to £18,720, against £18,213 for the corresponding period of 1894, an increase of £507.

HASTINGS AND ST. LEONARDS-ON-SEA ELECTRIC LIGHT COMPANY (LIMITED).—The annual report of the Directors of the above Company is issued. Although the Directors are unable to declare a dividend, they consider the Company to be in a sound financial position, the amount earned during the past year being £6,641, against £5,390 in 1894. Considerable expense has been incurred in the purchase of additional premises and new machinery. Owing to the change of electric supply from the high-tension direct-current system to the alterating high-tension transformer system, considerable outlay had to be incurred in alterations of conductors, fittings, &c., and this outlay had to be charged to the revenue account. The Directors, finding that installation work was not remunerative, have abandoned it and sold the stock-in-trade, and for the future intend to devote their efforts to the supply of current only. It is announced that a large reduction in the cost of current will shortly be made to large consumers.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic returns of this railway for the week ended the 19th inst. amounted to £1,141. The amount for the corresponding week last year (Whit week) was £1,282.

REUTER'S TELEGRAM COMPANY (LIMITED).—The following is the report of the Directors of this Company for the year ended December 31st last, to be submitted to the thirty-first ordinary general meeting, to be held at 24, Old Jewry, London, E.C., on Wednesday, the 29th inst., at 12 o'clock:—"The net profits from the telegraphic business for the year ended December 31st last, after payment of current expenses and deducting rebate on unexpired subscriptions, amount to £4,485. 15s. 9d. After deducting the sum standing to the debit of profit and loss account from the previous year, there remains a credit balance of £1,718. 16s. 5d., which is carried forward. The results would have been much more satisfactory but for the heavy expenditure entailed by the war between Japan and China. Although the Directors are unable to declare a dividend, shareholders will see from the figures for last year that the business of the Company is sound. Baron de Reuter seeks re-election as Director, as do the auditors, Messrs. Welton, Jones and Co."

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have ordered the following securities to be quoted in the Official List:—89,261 "A" shares (Nos. 1 to 89,261) and £100,000 Four and a-Half per Cent. Debenture Stock of the Edison and Swan United Electric Light Company (Limited), in lieu of the shares of the Swan United Electric Light Company (Limited), now quoted; and 3,000 Seven per Cent. Preference Shares (Nos. 1 to 3,000) and £60,000 Four and a-Half per Cent. Mortgage Debenture Stock of W. T. Henley's Telegraph Works Company (Limited).

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended May 17th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,584.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the half-month ended May 15th were £2,794, as compared with £2,510 in the corresponding period of 1894.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 889. [No. 5. Vol. XXXV.] FRIDAY, MAY 31, 1895. PRICE SIXPENCE.

NOTES.

A DISTINGUISHED diplomatist is stated to have given his valet strict orders never to disturb his diplomatic slumbers before 8 a.m. for anything short of a revolution. He was in consequence only once in his life up before eight. We are afraid it would fare exceedingly ill in this respect with any central station engineer or electric-light "undertaker" who should give orders never to be called before 8 a.m. for anything less than a new Board of Trade regulation. In another column we print the new rules for securing the safety of the public which have just been sent round to central station engineers and others for the purpose of eliciting any comments they may have to make. We trust the receivers of the latest official productions will tell the Board of Trade exactly what they think of them, and that both the Electrical Trades Section and the Council of the Institution of Electrical Engineers will do likewise. No good can come of futile grumbling. Much good might come of a round-table conference after the manner of that which brought about so many useful emendations to the original Board of Trade Electric Traction Rules. It is impossible that any official, however well qualified, should be able, without actual experience, to properly realise what is and what is not important, what is and what is not, humanly speaking, possible in the management and working of a modern electric lighting undertaking. Before the draft regulations become Board of Trade law, let the rulers and the ruled take friendly counsel together, and it will in all probability be found that the points of difference between them are neither so numerous nor so serious as was supposed.

THE Report of the Photometric Standards Committee, embodying the result of three years' careful investigation, has just been issued, and the recommendations they make with regard to a standard source of light may be confidently accepted as giving the best solution at present possible of this much-discussed problem. Their conclusions are in the direction in which general practice has been tending for some years past, namely, the adoption of a 10-candle standard produced by some form of flame. A portion of the luminous surface is all that is utilised, just as in the Methven standard, and the gas used in the burner is reduced to a constant luminiferous power by passing it, as in the Vernon Harcourt's standard, over the surface of liquid pentane before consumption in the burner. The height of the flame is adjusted to a fixed mark, although slight variations in this are not found to be important, owing to the fact that the area of the exposed part of the flame is quite constant. The form of instrument adopted is a 10-candle pentane argand burner designed by Mr. W. J. DIBDIN in 1886. The Committee have satisfied themselves that these burners can be reproduced in any quantities with sufficient agreement among themselves, and also that, as specified, the standard will give out light which is ten times the equivalent of the standard candle legally recognised for the last 35 years. One recommendation of special importance to the gas companies is that the illuminating power of coal gas shall be calculated, not as at present from the candle-power of a standard argand burner when burning the gas at a given rate, but from the rate of consuming gas when the burner is giving out a specified candle-power.

THE claims of an electrical standard of light have been considered and found wanting. The reasons are not stated, but probably the gradual change of the filament of a glow lamp with time formed the chief obstacle to its adoption. This alteration can be rendered small by under-running the lamp, but then the light given out is too red to be suitable as a standard. In any case the complication involved in the supply of electricity, adjusted, as it has to be, with the aid of a subsidiary electrical instrument, is almost enough to justify the recommendation of the Committee. The Dibdin standard is much more convenient, and is self-contained. It is possible to specify it completely, so that it can be exactly reproduced. With a glow lamp, on the other hand, the manufacture of the filament is not sufficiently under control, and its use as a primary standard appears impracticable, though it serves admirably as a secondary one.

MESSRS. HOUSTON and KENNELLY communicate this week a most useful contribution to the theory of permanent magnets. They show that there exists a factor of safety for magnets, by aid of which, in connection with the dimensions and quality of the steel, it is possible to state the degree of permanence of any particular magnet. They show how to calculate the demagnetising force due to the poles, and to compare it with the forward magnetising force, due to the induction density, determinable from the B-H curve for the particular steel of which the magnet is composed. The ratio of the latter force to the former they call the factor of safety, and experience shows that this should be at least 3 for

Digitized by Google

really good permanent magnets, and which, for the magnets of the well-known Weston instruments, amounts to as much as 6.

As the authors were beyond the reach of "proofs", we have printed their article in all its symbolic splendour and nomenclatural novelty. Every individual is, of course, entitled to have his own opinion as to the relative merits of "block" and "black" letters; but the use of "block" letters having become well established in this country, where modern Magnetism took its growth, we may be pardoned for refusing to countenance any further this anarchic tendency of every new writer on magnetic subjects to employ whatever symbols and terms seem good in his own eyes. The strange names which Messrs. Houston and Kennelly employ for the numerous magnetic units they refer to are quite unnecessary additions to the jargon of science, already sufficiently irritating, and they possess neither the sanction of authoritative nor of international usage, notwithstanding their adoption by the American Institute of Electrical Engineers. The hasty introduction of superfluous names and terms cannot be too strongly deprecated, both in the interest of science and of sense.

The word "gauss" has already been used for several different units; but never before, we believe, has it been employed in the same Paper with two distinct meanings. The authors employ it for both the unit of **H** and the unit of **B**. We venture to regard these two quantities as being as distinct from one another as amperes are from volts. While **B** is, perhaps, the magnetic quantity which can most easily be measured under all circumstances, **H**, on the other hand, is, we venture to think, the magnetic quantity which never has been directly measured. It has been calculated from the magnetising current, and has been determined from the mechanical force exerted on magnets suspended in air, or from the density of lines of force produced in air; but when we have to deal with a solid magnetic medium, there is no means, direct or indirect, of determining **H** at any particular point. All that is possible is to measure the magnetising current, and to calculate, by means of assumptions, an average value of **H**. It is convenient to adopt as our unit of **H** that magnetic force which will produce unit induction density **B** in air; but we have no right to regard the units of **H** and **B** as the same on this account. We might as well regard the volt and the ampere as identical, because the former produces the latter through a wire of unit resistance.

Our English dynamo designers will probably require additional information before they will be prepared to recognise the utility of Prof. Ryan's formulæ as to the heating of armatures, which we publish in another column. When the rise of temperature of any part of a dynamo is discussed, it is usually understood to mean its final rise in continuous working, or after a run of at least six hours at full load. But when Prof. Ryan comes to apply his formulæ to standard Edison machines he works out the rise of temperature for a two-hours' run at full load. The temperature of a 175-kilowatt dynamo after so short a run possesses little interest, since even a 50-kilowatt machine will continue to store up heat for over six hours. But it is of interest to note that 75°C. or 135°F. is regarded as a normal rise for the two-pole drum armature; a table is even given in the complete Paper on the assumption that this rise is attained after a two-hours' run. Does the American variety of dynamo permit of such a rise with impunity, while the English consulting engineer in our more equable climate usually specifies a maximum of 70°F. after six hours in full work? Again, a standard peripheral speed of about 3,000ft. per minute is assumed, whereas our predilection for direct-coupled dynamos leads to a large number of cases in which the surface speed is much less. A really satisfactory basis on which to estimate the cooling surface of armatures of different design and to allow for different speeds of rotation is, in fact, still to seek. Finally, the amount of the eddy-current loss in the core and winding is summarily disposed of by Prof. Ryan with the statement that it produces a rise ranging from 20°C. to 40°C. in the armatures under consideration. Yet if the formulæ and the conclusions thence deduced are to be of general use and validity, the width of the conductors and the question of whether they are solid or stranded are factors of such importance that they must be taken into reckoning. The proportion which the hysteresis and eddy-current losses bear to the loss by copper resistance will vary greatly in large and small dynamos, and even in machines of the same output at different voltages.

But though the theoretical starting point of Prof. Ryan may be questioned, the practical outcome of his Paper may be followed with advantage. It is to advocate short multipolar armatures of large diameter, in which the end-connections act efficiently as fans to carry off the heat from the winding and body of the core. Such a design is the natural complement of any method by which the sparking limit is raised, and Prof. Ryan's Paper, of which we recently gave a reprint, shows the direction in which he finds a solution to this latter problem.

Cable Interruptions and Repairs.—There are no interruptions or repairs to submarine cables to report this week.

Obituary.—A Reuter telegram from Madrid, dated May 25th, states that Lieutenant Peral, of the Spanish Navy, and inventor of an electric submarine boat, has died in Berlin after an operation for cancer.

Birthday Honours.—Amongst the numerous recipients of "Birthday Honours" we note the name of the late Director-General of Indian Telegraphs, who will in future be known as Sir William Brooke, K.C.I.E.

The Alternate-Current Transformer.—Mr. Gisbert Kapp has arranged with Messrs. Whittaker and Co. for a translation from the German of his new work on "The Alternate Current Transformer." It will be published in the "Specialists' Series" in the autumn.

Royal Society.—At yesterday's meeting of the Royal Society Mr. W. E. Wilson was down for the following Paper: "On the Effect of Pressure of the Surrounding Gas on the Temperature of the Crater of an Electric Arc Light. Preliminary Notes of Observations made at Daramona."

Technical Education.—Prof. W. T. A. Emtage, Professor of Mathematics and Physics at University College, Nottingham, has been elected, subject to the approval of the Technical Education Board of the London County Council, Principal of the Technical Institute, Wandsworth.

The Suez Canal and the Electric Light.—In the report of the Suez Canal Company for the year 1894 it is stated that 3,352 ships, of 8,039,175 tons, passed through the canal, conveying 165,980 passengers. Vessels to the number of 3,180 passed through at night by the aid of the electric light. The average time of transit was 19hr. 55min.

Electric Traction for the New York Elevated Railroad.—According to the Philadelphia correspondent of *The Times*, the Manhattan Elevated Railroad Company, which works the New York Elevated Railway, has decided to change its motive power to electricity, and is selling an issue of Manhattan Consolidated Bonds in London in order to provide funds.

A Statue to Lavoisier.—At the instance of the Académie des Sciences a Committee has been formed in Paris with the view of collecting subscriptions for a proposed statue in Paris in memory of Levoisier. It is intended to make the fund an international one as far as possible. Subscriptions are to be sent to M. Gauthier-Villars, 55, Quai des Grands-Augustins, Paris.

Argon.—The trustees of Columbia College, following the recommendation made by the National Academy of Sciences at their recent meeting, awarded the Barnard Medal to Lord Rayleigh for the discovery of argon. This gold medal is awarded every five years to the investigator who makes within the preceding five years the most valuable discovery in physics or astronomy, in accordance with the will of President F. A. P. Barnard, who died in 1889.

Institution of Electrical Engineers.—The following gentlemen were passed into the Institution at the last meeting:—Foreign members: Clarence L. Cory, Albert Petersen, John Kreuse, Charles Leblanc, Edward W. Mix, and F. W. Tischendœrfer. Member: Alfred Dickinson. Associates: F. Z. Maguire, Harold S. Adey, James T. Cornish, Charles Jefcoat, James E. Lea, B.Sc., Theodore J. Ridge, Arthur E. D. Saul, Philange Trackson, and Herbert Brandon White.

Lightning.—During a thunderstorm on Saturday last a flash of lightning struck the drying-house of a powder manufactory at Osenburg, near Halver, in Westphalia, causing an explosion. Considerable damage was done to the buildings, but no one was injured.——On Thursday, last week, three labourers were engaged in hoeing a field of wheat at Bardney Dairies, Lincolnshire, when the two outside ones were struck by lightning and killed. The centre man experienced not even the slightest shock.

The Berliner Patent in America.—In the suit brought by the United States Government against the American Bell Telephone Company, the owners of the Berliner telephone transmitter patent, with a view to having it declared void on account of illegal delay in its issue, the decision of the first Court, which was for the Government, has been reversed by the Court of Appeals. The patent was applied for on June 4, 1877, and was only issued on November 17, 1891. The Government has appealed to the Supreme Court.

Electrically Operated Bulkhead Doors.—A Reuter telegram from Washington states that since the disaster to the "Victoria" the officers of the United States navy have devoted much attention to the question of bulkheads. Chief Engineer Melville has now prepared several mechanical devices, which may be operated either by compressed air or by electricity, by means of which all the bulkhead doors of a vessel can be automatically closed at a moment's notice. The officer on deck or the man in the conning tower, on seeing the danger, can by simply pulling a lever close every door instantaneously, after first, by a prearranged whistle or bell signal, warning those below to hasten on deck or otherwise escape. The plan will be tested on board one of the new American warships.

Worcester.—With reference to the statements in local and gas newspapers, in regard to some mishap at the Worcester electric supply station, we are informed that the matter arose from "the failure of two new coils, which had been put into an armature," and that, "when the first coil went, two machines were in parallel, and the faulty machine was switched out before further damage was done. The coil in the second machine went before there had been time to parallel another machine." We are promised further particulars from the contractors as soon as the matter has been thoroughly investigated. The mishap occurred last Wednesday week.

The Series-Parallel Control.—An American patent of Dr. John Hopkinson, claiming the series-parallel coupling of electric tramcar motors, came into "interference" with a similar patent granted to one Rudolph M. Hunter, and the question has been adjudicated upon by the American Patent Office. "While awarding Dr. Hopkinson the claim to priority, the examiner," says the *Electrical Engineer* of New York, "draws attention to the fact that the patent for which Dr. Hopkinson applied in the United States was in public use upon the Lehigh Avenue Railway, in Philadelphia, in the month of May, 1890, and hence comes under the law forbidding the issuance of a patent for an invention in use two years prior to the date of application therefor. From the opinion of the Patent Office examiner it would seem that the 'series parallel' method of coupling street railway motors was public property."

The China-Burma Telegraph Line.—A copy of the convention between Great Britain and China respecting the junction of the Chinese and Burmese telegraph lines, signed at Tientsin on September 6, 1894, has just been issued as a Parliamentary paper in the Treaty series. The junction is to be effected, according to the convention, between the British station at Bhamo and the Chinese station at Tingyueh (Momein), at the latest on May 31st, this year, unless this should be prevented by accident or by *force majeure*, and in that case as soon as possible thereafter. Each of the contracting parties is to bear the expense of establishing, working, and maintaining in good condition the line of connection incurred on its own territory. The rules for the extra-European system laid down in the service regulations of the International Telegraph Convention are to observed with regard to the telegrams transmitted between Bhamo and Tingyueh, but in reckoning the number of words in telegrams between China or Hong-kong on the one side and Burma, India, or Ceylon on the other, the rules of the European system are to be observed. The detailed charges per word levied by the Indian and by the Chinese telegraph administrations respectively are given, and it is provided that these charges are not to be raised before January, 1897, though they may be reduced.

Imperial Postal and Telegraph Routes.—On Friday last a deputation from the Association of Chambers of Commerce of the United Kingdom waited upon the Prime Minister with the object of bringing under notice the following resolution passed at the autumn meeting of the Association at Huddersfield:—"That this Association expresses its hearty approval of the resolutions adopted by the Inter-Colonial Congress recently held at Ottawa in favour of inter-Imperial postal and telegraph routes between this country and the Colonies and between the Colonies themselves respectively without such routes passing through other countries." Sir Albert Rollitt introduced the deputation, and spoke on behalf of the resolution. Mr. Thompson, of the London Chamber of Commerce, commented on the difficulties which he thought would ensue from our present telegraphic position in case of war. He was of opinion that the simple way of counteracting this danger was lay a cable between Vancouver and Australia. The Prime Minister, in reply, said that an inter-departmental committee, consisting of representatives of the Treasury, Post Office, and the Colonial Office, had been appointed, and was now considering the concrete recommendations of the Ottawa Conference, and until this Committee reported it would be impossible for him to express any definite views on the subject brought to his notice by the deputation.

A Century of Science. The *Philosophical Transactions* of the Royal Society, extending over a period of well-nigh a century (1800—1895), have recently been indexed in a handy little Catalogue of some 100 pages. The indexing is by alphabetical arrangement of the authors' names, and each item is accompanied by the price at which the Paper is published by Messrs. Dulau and Co. Within the limits of this scarcely completed century, and on the pages of this little pamphlet, are names which stand out as landmarks of progress in science.

Digitized by Google

Some of the items enumerated are quaintly interesting; and in those which are of electrical or engineering interest, the stages of development of these branches of technology are clearly defined. We may notice one or two of the early Papers. In 1801 "An Account of Some Galvanic Combinations, formed by the Arrangement of Single Metallic Plates and Fluids, analogous to the New Galvanic Apparatus of Mr. Volta," was contributed by Sir Humphrey Davy. In 1834 Sir Charles Wheatstone gave "An Account of Some Experiments to Measure the Velocity of Electricity, and the Duration of Electric Light." In 1865 Clerk Maxwell read the Paper on his famous "Dynamical Theory of the Electromagnetic Field," and two years later he gave his account of "The Dynamical Theory of Gases." The researches of Faraday occupy nearly two pages, and we find also in handy columns the Royal Society works of Thomson, Rankine, Joule, Cayley, and others, besides later scientists, such as Hopkinson, Ewing, Crookes, &c.

Institution of Civil Engineers.—The annual general meeting of this Institution was held in the Hall of the Royal United Service Institution, on Tuesday, the 28th inst, Sir Robert Rawlinson, K.C.B., President, in the chair. The Report of the Council commenced by referring to the change that had taken place in the roll of the Society during the past twelve months, during which 29 members, 286 associate members, and five associates had been elected. The net increase was 155, or at the rate of nearly 3 per cent. per annum. The numbers of all classes on the books at the end of the Institution year were: Honorary members 17, members 1,862, associate members 3,687, associates 355, making a total of 5,921. For the first time since the introduction of the higher qualifications of candidates for admission as students, the Council was able to report an effective increase in the roll, the numbers on March 31, 1895, being 816, or 25 more than at the same date last year. The statement of accounts showed that the receipts of the year had been altogether £30,318. The general expenditure amounted to £18,385. The completion was announced of the new Library Catalogue, comprised in three volumes, copies of which would be issued to public libraries and those of educational and scientific bodies in all parts of the world. The Council had given considerable attention to the question of enabling all entitled to vote at the annual election to exercise that privilege whether present at the meeting or not. The opinion of counsel was, however, that under the existing charters such votes could only be given personally.—The ballot for Council resulted in the election of Sir B. Baker, K.C.M.G., as President; of J. Wolfe Barry, C.B, W. H. Preece, C.B., Sir Douglas Fox and James Mansergh as Vice-Presidents; and of W. Anderson, Alex. R. Binnie, W. R. Galbraith J. H. Greathead, J. C. Hawkshaw, C. Hawkesley, Dr. John Hopkinson, Alex. B. W. Kennedy, Sir G. L. Molesworth, K.C.I.E., Sir Andrew Noble, K.C.B., Sir E. J. Reed, K.C.B., M.P., W. Shelford, F. W. Webb, Sir W. H. White, K.C.B., and Sir E. Leader Williams.

The County Council and Transformer Chambers.—At the weekly meeting of the London County Council last Tuesday, the Highways Committee reported on a difference that had arisen between the Council and the House-to-House Electric Light Supply Company, with reference to the construction of transformer chambers. Last February the Council, in giving sanction to certain works of the Company, expressly withheld sanction to the construction in Kensington High-street of a transformer chamber of the inside dimensions of 5ft. by 6ft. 6in, and between 6ft. and 7ft. deep. The Company gave notice on May 14th that, as its system of supply had received the provisional approval of the Board of Trade, it intended to proceed with the construction of the transformer chamber, and by their direction the Council's solicitor warned the Company that, as it had not appealed to the Board of Trade, it had no authority to proceed with the work. The Company had since intimated its intention to appeal; but had also, with the view of meeting the objection of the Council, offered to place the proposed chamber in Wynnstay-gardens, a position which was certainly less objectionable than that first proposed. The Council had consistently objected to the construction of large transformer chambers under the public thoroughfares, and the Committee did not see any reason for an exception being made in this case. They therefore recommended that the Company be informed that the Council was not prepared to depart from its previous decision, and that they left the matter for the decision of the Board of Trade upon appeal. This was agreed to. The Council also formally disapproved of applications from the County of London and Brush Provincial Electric Lighting Company to construct 42 transformer chambers in St. Luke's and 34 transformer chambers in the Wandsworth district.

Hong Kong Electric Supply Station.—The supply station at Hong Kong has now been in operation for four and a-half years, the public lighting having been started in December, 1890. The station is situated at the east end of the town of Victoria. It is built on the side of the hill, the ground having been arranged in two terraces, on the upper of which the engine room is built, and on the lower the boiler house, stores and offices. The engine room contains five horizontal compound engines, with jet condenser at back of low-pressure cylinder. The engines run at 100 revolutions per minute. The flywheel, which is between the high and low-pressure engine is 13ft. in diameter, with six grooves on the face for driving ropes 1¼in. diameter, leading direct to the countershaft for driving the dynamos. There are two feed-water heaters. The water supply for the condensers is obtained from a tank of about 30,000 cubic ft. capacity, dug out of the hill, and fed by a small stream. The boilers are supplied either from this tank or from the town supply. The boiler house contains three steel Lancashire boilers with Galloway tubes. The boilers are 26ft. 6in. long, and are worked at a pressure of 140lb. They are supplied with water by injectors and two donkey pumps. As a rule only one boiler is in use, but a second is kept under steam in case of accidents. Japanese coal is used, and although rather smoky gives very little trouble in keeping steam. The three arc light dynamos, which are fitted with automatic regulators, are each of 55 lights capacity, and are run off a countershaft by belts. Two horizontal and one vertical engine work on to the countershaft, and each pulley on the countershaft is controlled by a patent friction clutch so that any engine or dynamo can be changed while running without interrupting the lights. The alternators are 50 kilowatt Kapp type, running at 650 revolutions per minute, with 75 $\sim$, and giving 2,000 volts; and they are placed on slide rails. They are excited by Kapp dynamos, giving 50 amperes at 150 volts, driven by belts off the alternator shafts. Transformers transforming from 2,000 to 100 volts are used in the houses for private lighting. The switchboard, which is at the back of the engine room, is of teak, and is about 3ft. away from the wall, thus allowing access for connecting up the leads. Lightning arresters of the magnetic air-gap type are placed on each pole of every circuit. These were adapted in preference to the Brush type, which did not answer in the severe storms which Hong Kong is subject to, and it was no uncommon thing to have the arc circuits struck and short-circuited twenty or thirty times in an hour during a heavy storm. Sometimes it was impossible to keep the incandescent circuits going, as the fuses were blown as fast as they were replaced, owing to the lines being repeatedly struck. After the adoption of magnetic arresters and Wurtz arresters at intervals along the lines, there was seldom any mishap. The principal streets are lit by 80 double-clutch non-focussing Brockie-Pell arc lamps. These are fixed in carriers, with a reflecting hood, and placed on top of iron lattice poles 40ft. high, except in a few cases where shorter poles were found necessary. These posts carry wrought-iron brackets, on which are fixed insulators to carry the cables both for the arc lamps and incandescent circuits. Messrs. Johnson and Phillips' fluid insulators are used for carrying the stranded steel bearers. The cables, which are $\frac{7}{16}$in. stranded wire, are of high-insulation vulcanised rubber, and are suspended from the steel bearers. An earth wire connects all the poles and lamp posts together to guard against lightning. There are two incandescent and two arc-light circuits. In all about 10,000 lamps are in use in the official and private residences. The station and works were equipped throughout by Messrs. Johnson and Phillips, to the designs of Mr. J. W. Hart, and were erected under the personal superintendence of the present manager, Mr. W. H. Wickham,

MOTIVE POWER AND GEARING.*

BY F. TREMLETT CARTER.

(*Continued from page 5.*)

Hornsby Horizontal Compound Engine.—At the Paddington station of the Metropolitan Electric Supply Company there are five Hornsby horizontal compound non-condensing per minute. Each dynamo has a normal output of 120 kilowatts; so that the normal effective power of each steam engine is about 190 B.H.P., and the total power about 210 to 220 I.H.P. Elevation and plan of one of these engines—all five are similar—are shown in Fig. 67, the plan also showing a section of the cylinders and valves. The stroke of each piston is 27in. The diameter of the high-pressure cylinder is 15in., and that of the low-pressure cylinder 24⅛in. The cranks are set at 90°, and there is a receiver between the

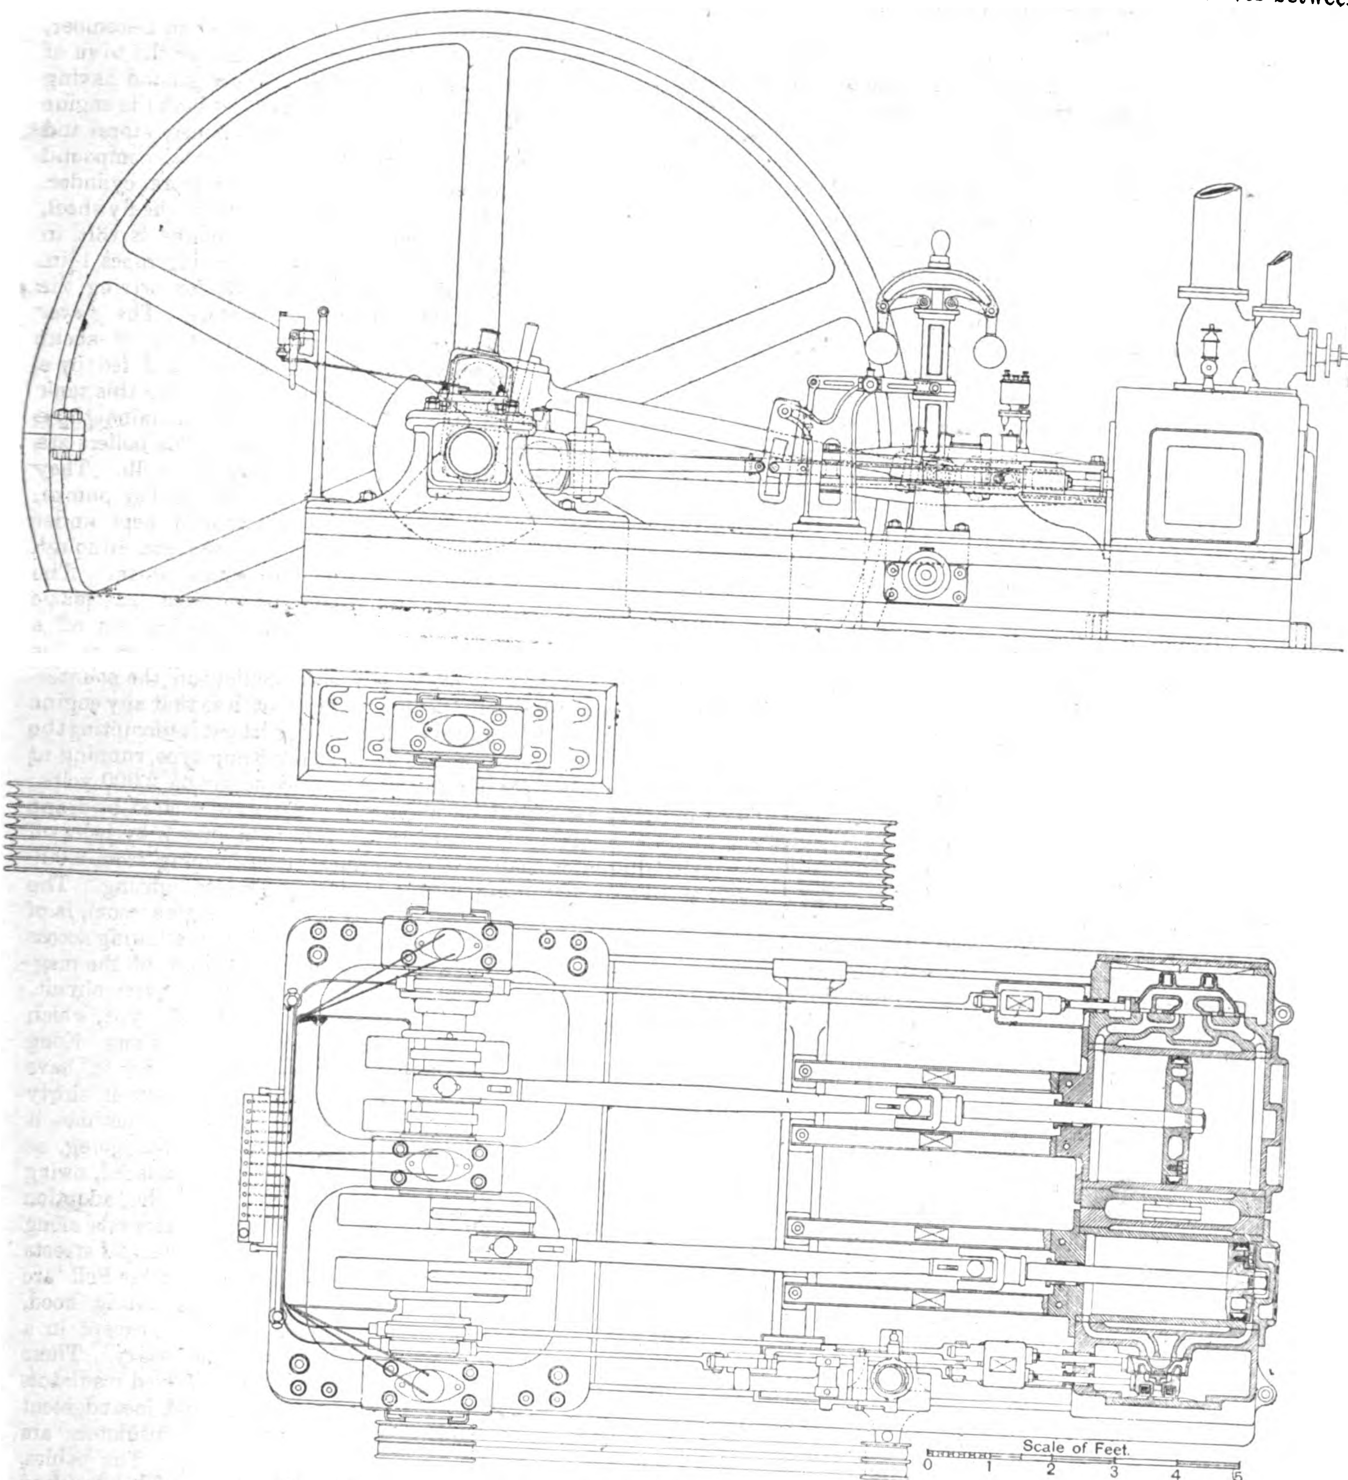

FIG. 67.—Side-by-Side Horizontal Compound Engine.—By R. Hornsby & Sons.

engines. Each of these engines is coupled to a separate alternator, by means of eight 1⅜in. ropes, the length of the drive being about 25ft. between centres. The engine fly-wheel is 14ft. in diameter, and runs at 100 revolutions per minute; the dynamo shaft is run at 600 revolutions

*From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

cylinders which is not shown in the drawings. The distribution of steam in the high-pressure cylinder is controlled by an automatic expansion valve, actuated by a governor through a vibrating link, after the manner of the Hartnell gear shown in Figs. 57 and 58 (see Vol. XXXIV. p. 698). The distribution of steam in the low-pressure cylinder is effected by a single Trick valve, and does not vary with the load. Both cylinders are

Digitized by Google

steam jacketed, and the initial pressure of the steam admitted to the high pressure cylinder is 160lb. on the gauge. The governor is driven by two belts from a flanged pulley, and, to minimise hunting, is fitted with an oil cataract. The lubrication for all the working parts, with the exception of the governor and the cylinders, is effected by a system of pipes supplied from one oil reservoir at the front of the engine. Besides the separate cocks on the several cil pipes, there is one master cock by which the lubrication of the entire engine may be controlled. This lubricating apparatus is shown in under a jockey pulley; and the length of the drive is only 11ft. 4in. between centres. A side and an end elevation of one of these six similar engines are shown in Fig. 68, the latter view also showing a section through the cylinders and valves. The engine is designed to give 90 B.H.P. when supplied with steam at 120lb. on the gauge. It is coupled to a Ledward ejector condenser, shown in the side view (see also Fig. 45). The speed of the engine is designed to vary between 120 to 135 revolutions per minute, according to the load on the five-wire electric mains to which the engine supplies power.

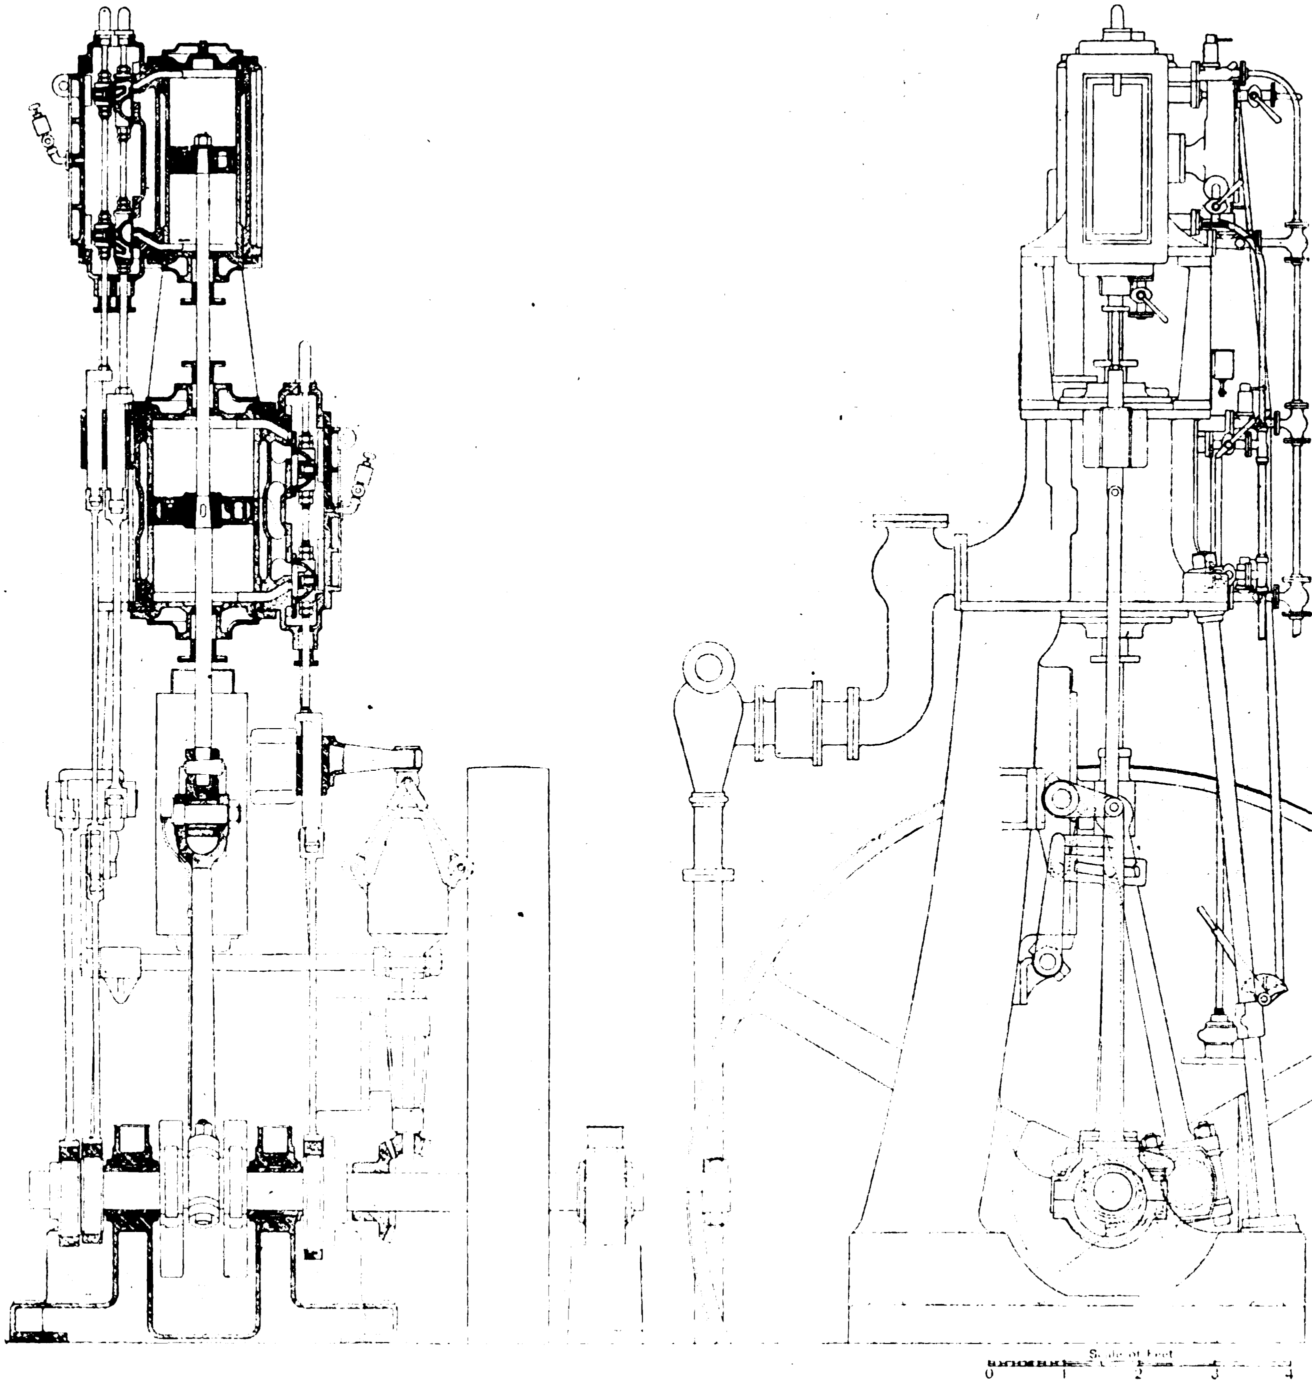

FIG. 68.—Vertical Tandem Compound Engine.—By R. Hornsby & Sons.

the drawings, at the extreme left of the bed-plate. These engines were built by Messrs. R. Hornsby & Sons (Limited), of Grantham.

Hornsby Vertical Compound Engine.—At the electric supply station of the Manchester Corporation there are, besides other engines, six vertical tandem compound condensing engines, built for this station by Messrs. R. Hornsby & Sons (Limited). Each of these engines drives a separate continuous-current dynamo, by means of link belting passing

This method of regulation is described on page 61 of Vol. XXXIV. The speed is varied by hand while the engine is running, by varying the weight on the dead-weight governer which actuates the cut-off in the high pressure cylinder. The governor controls the expansion valve by means of an efficient and special form of link motion, the details of which are shown in the drawings. The governor is of the Porter type, and is driven from the engine shaft by bevel gear, without belt or rope gear; it is therefore certain and steady in its action.

cylinder 16in. Both cylinders are steam jacketed. A perspective view of this engine, as erected at Manchester, is shown in Fig. 69.

(To be continued.)

ATMOSPHERIC ELECTRICITY.*

BY PROF. A. SCHUSTER, F.R.S.

(Concluded from 115).

Brief allusion must be made to some of the causes which alter to a marked extent the normal fall of potential. As the surface of the earth is negatively electrified, it follows that dust carried up by the wind must be electrified, and it is found, indeed, that in violent dust storms the laws of force near the surfaces are altogether distorted and reversed in direction. Werner Siemens† (*Pogg. Ann.*, CIX., 1860) could, while standing on the top of one of the pyramids during a strong wind, charge an improvised Leyden jar sufficiently to obtain strong sparks. A casual observation of Elster and Geitel,‡ may prove significant. On March 7, 1889, the temperature in Wolfenbüttel was rising from $-10°C$ to $+2°C$, a cirrus layer covering the sky. The fall of potential changed in the course of four hours from 1,302 volts per metre to $-1,200$ volts, that is, from a very exceptionally high fall to an equally strong gradient in the other direction. Although the atmospheric circumstances were anomalous, they seem not in themselves sufficient to account for the anomalous electrical effects, and the authors suggest that a possible explanation may be found in a violent dust storm which on the previous day was observed in Alexandria.

Fogs are generally found to increase the normal fall considerably, so that the drops of water must be taken as positively electrified.

Waterfalls considerably disturb the electric condition in their neighbourhood, the air surrounding the fall being found charged negatively sometimes to considerable distances.

Whether clouds in themselves are always electrified is very doubtful; they no doubt disturb and generally weaken the fall of potential at the earth's surface, but this may only be due to a displacement of the positively-electrified layer which balloon observations have shown to exist at a height of from 10,000ft. to 20,000ft. While a cloud discharges rain, the electrical effects in the neighbourhood of the place are the same as that in the neighbourhood of a waterfall. The explanation is probably the same in the two cases, and by means of experiments, alluded to further on, we may reproduce the negative electrification of air under similar circumstances.

Measurements of the electrification of falling rain or snow simple as they appear at first sight, are beset with very serious difficulty. We owe the most complete investigation on the point to Messrs. Elster and Geitel.* They find no regularity in the electrification, though positive signs slightly preponderate with snow and the negative signs with rain.

The approach of a thunderstorm announces itself by characteristic cumuli clouds, and the general atmospheric condition favourable to their formation is felt by many persons of nervous temperament. Many of us are accustomed to hear that "there is thunder in the air." Whatever the special feeling of "thunder" may be due to, it cannot be an electrical effect, for electrical instruments, delicate enough to detect a small fraction of the normal stress, give no indications of the approach of a thunderstorm, and it is only when the cloud has begun to discharge rain or hail that strong electrical effects are noticed. During the thunderstorm the electroscope is, of course, much disturbed, and there are frequent and violent reversals of its indications.† The fact that no effects are observed at the surface of the earth during the approach of a thunder cloud does not prove that there is no electrical separation, for we may imagine two oppositely electrified layers at different levels producing a strong electric field between them, but only weak effects outside. That some such thing may possibly occur is indicated by observations made in mountain districts, where violent electrical disturbances are observed previous to the formation of clouds.‡ The cumulus cloud, from which the lightning strikes out, is nearly always associated with a cirrus layer above it, and the flash occurs more frequently upwards or sidewards between the clouds than down to earth. Under such circumstances it is clear that instruments on the surface of the earth can only very partially indicate the nature and distribution of electrical stress in the neighbourhood of the cloud.

Thunderstorms seem always to be connected with a vortex motion, and meteorologists distinguish two kinds of thunderstorms. The first kind forms in the outlying portions of a large cyclonic system. The storms which occur chiefly in winter are of this nature, and the vortex necessary for its formation is of the nature of a secondary disturbance. The thunderstorm which forms in summer, on the other hand, makes its own vortex, and is of a much more local nature than that which is produced round a previously-established barometric depression. The summer storm is much influenced by the character of a district. There are certain configurations apparently favourable to its formation, as is clearly brought

out by the charts which have been made representing their frequency.

The route travelled over by the storm is affected by mountain ridges, and rivers also seem to offer a peculiar impediment. Many of them are brought to an end either along their whole front, or only part of it, when they reach the banks of a large river.*

Some curious problems are presented by the detailed structure of lightning flashes. Although these lie outside the range of the present lecture, reference must be made to the very beautiful photographs of lightning flashes taken both in this country and abroad. The ordinary forms which lightning takes are familiar to all; but a good deal of mystery still surrounds the so-called globular lightning. The manner in which this form appears is best described in the words of eye-witnesses.

Dr. A. Wartmann gives to the Physical Society of Geneva the following account of what he saw† :—"At half-past six o'clock in the evening I drove from Versoix to Genthod. On the Malagny-road, I heard the coachman say he did not know where he was. His eyes were so much fatigued by the frequent and intense lightning discharges, that he was blinded, and could not, even in the intervals, see the road, in spite of the good lanterns along it. I stepped on to the box and took the reins. We had barely passed the principal gate of the grounds of Dr. Marcet, when I became conscious of a bright and lasting luminosity behind me. Thinking it was a fire, I turned round, and saw, at a distance of, roughly, 300 metres, a ball of fire of about 40cm. diameter. It travelled in our direction with a velocity about equal to that of a bird of prey, and left no luminous trail behind. Just as the ball had overtaken us, about 24 metres to our right, it burst with a terrific noise, and it seemed to me as if lines of fire started from it. We felt a violent shaking, and remained blinded a few seconds. As soon as I regained power of distinguishing objects, I saw that the horses had turned at a right angle to the carriage, with their chests in the hedge, with drooping ears and all signs of great terror. I returned on the following day to the place where I had seen the ball explode, but could find no sign of any damage. At a distance of 100 metres I found that a group of three trees, bordering a wood, had their upper branches singed, but it is not possible to say whether this was due to the discharge which I had seen."

The following is a translation of an account given by Mr. H. W. Roth‡ :—"During the thunderstorm of May 19, 1888, at about 6 p.m., a flash of lightning took effect which seems to me remarkable from a physiological point of view. The dealer Werner, from Ellerbruch, and his son (16 years old), were at the time on the road which leads from here to the village of Ottensen, with a one-horse conveyance containing rags, about three miles away in a south-westerly direction. The father had been left behind a little, and the son was occupied in giving bread to the horses, when he found himself suddenly surrounded by light, and noticed a fiery ball, about the size of his fist, move towards him along the back of the horse. Then he lost consciousness. He felt no concussion. The father, approaching, still saw the horse's limbs contracting, and at first he thought his son was dead, but succeeded, after all possible efforts, in bringing him back to life in about three-quarters of an hour. The horse was dead."

Some curious statistics have been collected, especially in Germany, as to the damage done by lightning flashes. That damage seems to have increased to an enormous extent within the last 50 years, and although in cases of this kind statistics may easily be at fault, there seems no doubt about the reality of the fact, which may find an explanation in the partial cutting down of forests in those parts where thunderstorms chiefly occur. When lightning strikes into forests, it selects certain trees by preference. Thus, in the principality of Lippe, taking the percentage of beeches struck by lightning as unity, that for other trees is as follows:—Oak 48, pine 5, Scotch fir, 33.

* Bebber, "Meteorologie," p. 255. Bornstein, "Archiv. der Seewart, VIII." (1885).

† "Arch. des Sc. Phys. et Nat." (3), Vol. XXI. (1889). The above account is translated from the *Meteorologische Zeitschrift*, 1889,

‡ *Meteorologische Zeitschrift*, 1889, p. 231.

The St. Elmo's fire, a continuous discharge from points and sharp angles, is often observed on board ship and in mountain districts during a storm. Its appearance was considered a sign of the approaching end of the lightning, and was looked upon with favour by the ancient sailors in the Mediterranean Sea, who gave to it the name of Castor and Pollux. There was another appearance called Helena, a bad omen, which by many is believed to have been another form of the St. Elmo's fire, and the present name has been stated to be a corruption of the word Helena. Some support is given to this view by the fact that the Emperor Constantine built a castle in the Pyrennees, which he named after his mother, Helena, and this castle seems to be referred to occasionally as St. Elne or St. Elme. But it is much more probable, as argued by Dr. F. Piper,* that the word is derived from St. Erasmo, a bishop who came from Antiochia, and suffered a martyr's death at the beginning of the fourth century. He seems to have been specially considered the patron of Italian sailors. Churches and castles in Naples and Malta were called St. Erasmo and St. Ermo, and Ariosto describes St. Elmo's fires as St. Ermo's fires. The electric discharge which goes under this name has a different appearance according as it is the positive or negative electricity which escapes, and both kinds occur with about equal frequency.

Although we have not yet arrived at any satisfactory theory of atmospheric electricity, some progress has been made, and this account would not be complete without a short account of the views taken by men of science on the subject. The number of theories proposed is very considerable. Dr. Suchsland,† in a pamphlet published in 1886, gives an account of 24, to which he adds one—his own. The year 1884 alone has given birth to four theories.

We may group the theories according to the origin they assign to the source of energy which is involved in the formation of the electric field. All the work we can perform is either derived from the sun or from the earth's rotation. There is, as far as I know, only one theory—that of Edlund—which makes the earth's rotation in space responsible for the separation of electricities in the atmosphere. But Edlund's views are not tenable in theory, and, even granting his deductions, the normal fall of potential should, according to the views of the author, have a different sign in the polar and equatorial regions, which is contrary to the observed fact. This theory does not, however, exhaust the possibility of explaining atmospheric electricity as a phenomenon of electromagnetic induction, and it is not disproven that in some form or other the rotation of the earth's magnetic field may play a part in the origin of the electric field. The theories which take solar radiation as the source of the energy divide themselves into several groups. We may think of a direct thermo-electric or actinic action, but there is, so far, no experimental support to such views. One of the earliest and most natural suppositions is the belief in evaporation as a source of electrification. This was Volta's theory, and experiments have at various times been produced in its support; but, so far, no one has been able to invalidate Faraday's conclusion that whenever electrification seemed to appear as a consequence of evaporation, it was really due to secondary causes, such as the friction of the liquid spray against the sides of the containing vessel. Rejecting Volta's theory, there is nothing left but the belief in some form of contact or frictional separation either between drops of water and air, or water and ice, or any two of the various bodies present in the atmosphere. The possibility of contact electricity, between a solid or liquid, and a gas, is not quite easy to submit to the test of experiment. If we rub two solid bodies together we may, by separating them, investigate the electric field produced; but, supposing we have a drop of water surrounded on all sides by air, the water may be covered with an electric layer of, say, positive electricity, the air in contact with the water with the opposite kind, and it is not at all clear how we could experimentally demonstrate the difference of potential between the air and the drop which is thus produced. A current of air flowing past the

† "Die Gemeinschaftliche Ursache der Elektrischen Meteore und des Hagels." (H. W. Schmidt, Halle-a.-S.)

Digitized by Google

drop might carry away some of the negative layer, and in this way an electric field may be established while clouds are forming, but the conditions necessary for an experimental demonstration would be very difficult to realise. Two methods have been devised which practically demonstrate some form of contact electricity between gases and water.

Lenard, wishing to imitate the electric field observed in the neighbourhood of waterfalls, has established by careful experiment a number of important facts, which are all consistent with the following explanation. If we imagine two oppositely electrified layers at the surface of a drop of water such as has been referred to, and if the drop falls on to a layer of the same liquid, or if similar drops impinge on each other, the difference of potential produced by the fusion of the surface layers becomes greater than is consistent with equilibrium. For, taking the case of drops falling into a mass of water contained in a cylindrical vessel, the extent of surface between air and water is not increased by the falling drops, and we must imagine that surface to be already covered with a sufficient electrical sheet to establish the required difference of potential. The electrification of the drops is, therefore, not wanted, and a change in the distribution takes place. The natural supposition would be, that this equilibrium would be restored very quickly through the surface of the water, but a sufficient time seems to be required for the surplus electricity to be blown away by the strong current of air which in Lenard's experiments is brought down with the water drops. The air, passing out sideways, is negatively electified, and the water remains positive. More recent experiments of Lord Kelvin's, with air bubbing through water, point similarly to contact forces between gases and liquids, and in these experiments also it appears that a considerable time is required to establish electric equilibrium between a gas and a solid. Lenard finds very important differences caused by small impurities in the water, the water acting much more strongly when it is pure. If it contains as much salt as is contained in the sea, the effect is reversed, and the air becomes positively electrified. The explanation which is given above is practically that of Lenard, whose observations have been confirmed and further extended by Prof. J. J. Thomson. These experiments, no doubt, account for the behaviour of air in the neighbourhood of waterfalls, and they probably also explain the negative electrification of air in the neighbourhood of districts in which rain is falling. The strong positive electrification of mist may also be due to the same cause.

There seems to be no doubt that the formation of cloud is often accompanied by electrical effects. A few years ago, descending from Dent Blanche, I found myself, after sunset, at a height of about 12,000ft. A current of air was apparently blowing up the valley, which reaches from Evolena towards Ferpecle, and I could observe below me the formation of a cloud at a height a little below the snowline. As night came on, and we continued our descent over the glacier and down the valley, a series of electric discharges were noticed between the cloud, which was lying in a deep-cut valley, the sides of the mountain, and the blue sky overhead. Here the moist air was evidently flowing through the cloud, depositing its moisture in the form of drops, and it seemed the most natural explanation at the time that the air left the cloud in an electrified state. But while by means of experiments we have been able to produce some of the phenomena of atmospheric electricity, we have other important effects which cannot be accounted for in so simple a way. The electric discharges during a thunderstorm give evidence of electric fields, which could hardly be explained by contact electricity between drops of water and air alone. The fact that thunderstorms are nearly always connected with the formation of hail, and Faraday's experiments showing that water rubbing against ice becomes negatively electrified, is made use of in the theories of Sohnke and Luvini. It is quite likely that there is some truth in these theories. Their weak point lies in the difficulty of seeing how particles of ice and water can be first sufficiently mixed to allow of friction, and then become sufficiently separated to produce an electric field of such magnitude as we know must exist in a thunder cloud. It is to be remarked, however, that the laws of contact electricity must be applicable to gases as well as to solids, and that if water becomes positive when rubbing against air, and negative when rubbing against ice, there must be a strong contact difference between ice and air. In other words, it does not matter whether there is direct friction between ice and water, or whether the air forms an intermediate body. We may imagine air rising through a cloud containing drops of water becoming negatively electrified, and then passing through an ice cloud having its negative electricity increased, thus leaving the ice and water particles at a difference of potential which may, by a fusion of the drops, increase sufficiently to produce a lightning discharge. This seems to the writer the most plausible theory which, in the present state of our knowledge, can be formed. As regards the permanent negative charge of the earth's surface, the time has not yet arrived for forming a definite opinion. Because, although we know that the earth, once electrified, would gradually lose its charge into the atmosphere, yet we can express no opinion as to the rate at which the loss is going on. That loss may be exceedingly slow, and consequently equilibrium might be attained by a very small preponderance of negative electricity brought back to its surface through some cause or other. Rain, as has already been mentioned, is more frequently electrified negatively than positively in our own climate, and though we do not know how far this holds in the tropical belt, it is at any rate possible that the surface of the earth may in this way alone make up for the loss. We may also reasonably think that Lenard's observation on salt water may account for the permanent charge. Every wave that breaks into spray under the action of a strong wind would leave the water negatively electrified, the air carrying away the positive charge. It would be of great interest to possess observations on atmospheric electricity on board ship while waves are breaking in the neighbourhood. So far we have only Exner's observations to guide us, who found, while observing at Lavinia, in Ceylon, that the spray from breaking waves affected the indications of the electrometer, proving its positive electrification.*

But although the loss of electricity of the earth's surface may be very slow, it is equally possible that it is considerable. We shall not be able to treat this question satisfactorily until we have some clearer notion of the causes of the aurora. We know that the aurora implies electric currents, and the circuit of these currents may lie completely within the earth's atmosphere, and have nothing to do with the observed fall of potential near the ground. It is also possible that the body of the earth forms part of the electric circuit, and if that is the case, there must be across different parts of the surface an outward and inward flow of positive electricity. Such a discharge could not fail to affect profoundly the phenomena we have discussed, and it seems probable that we should have some evidence derived from observation if the aurora necessarily involved discharges through the earth's surface. Except in the polar regions, these auroræ do not seem to affect the normal fall of potential. There is a third view we may take as to the circulation of electric currents indicated by the aurora: the return current may take place in space outside the earth's atmosphere. A good deal might be said in favour of this view, and the rotation of the earth's magnetic field in space might be a sufficient cause for the production of these currents; but this is not the place to enter further into this question.

Calculations made from observation on the height of the aurora have generally resulted in an altitude of from 100 to 200 miles, except in the polar regions, where the aurora seems occasionally to descend to a much lower level. It has also been noticed that auroræ are associated with certain bands of cirrus clouds, and this seems to indicate that although the luminous phenomenon is sufficiently intense to be observed only at great heights, yet the electric phenomena may descend to the level of the cirrus.

As regards the connection between the aurora and the sunspot period, further observations in the polar regions are needed. On the one hand, we have Paulsen's† statement,

* *Wiener Akad. Sitzungsberichte*, Vol. XCVIII.

† Paulsen, "Danske Videnskal. Selskats Forhaud," 1889. (I have not seen the original memoir, but only an abstract in the "Jahrbuch der Astronomie und Geophysik, 1890.")

Digitized by Google

derived from observations in Greenland, to the effect that the greatest number of auroræ are seen when sunspots are at their minimum, that is, at a time when in our own latitudes the number is smallest; and, on the other hand, we have Nordenskiöld's observations, which seem to point in the opposite direction. In a publication which contains much important matter on the geographical distribution and form of the aurora borealis, Nordenskiöld contrasts the appearances he has observed in the Vega during the winter of 1878-79, passed in the Behring Straits, with that previously observed in 1872-73 to the north of Spitzberg. According to this author, the aurora, during the minimum sunspot period in 1878-79, were "hardly worthy of his notice by the side of those observed in 1872-73." But, although only faintly luminous, the auroræ of 1879 were persistent and regular in shape. They did not affect the magnetic field, and seem to show a regular and continuous, though weak, electric discharge. The arc and streamers in 1872 were much more brilliant and much more irregular. Some objection may be raised against these observations, in so far as they refer to different places, and local circumstances may have affected the phenomenon; but in the face of the very careful description he gives us, we cannot as yet accept Paulsen's results without further confirmation.

The problem of atmospheric electricity, like that of terrestrial magnetism, presents special features in the arctic regions, and until we possess a greater number of observations in those little accessible parts of the earth's surface, many important problems cannot be satisfactorily solved. Arctic and Antarctic expeditions are of interest to scientific men, not because they care much whether we get a few miles nearer the pole, but because a well-conducted party collects invaluable information on its journey. Although much remains to be done in the regions surrounding the north magnetic pole, our knowledge in the southern hemisphere is almost disgracefully inadequate, and it is to be hoped that before long a well-equipped expedition may fill up to a certain extent the large gaps in our electrical and magnetical knowledge which at present stop so many of our researches.

But although investigations to be conducted in the Arctic regions are of primary importance, we may do much nearer home in extending and completing existing information. Instrumental appliances and methods of observations, originally put into a satisfactory state by Lord Kelvin, have been improved, especially by Mascart, Exner, Elster and Geitel. One of our most crying wants at present is a series of continuous observations by means of self-registering instruments in places where the neighbourhood of a town, or other local circumstances, do not interfere with the normal changes. The Greenwich Observatory, to whom we look for help in such matters, is placed in the difficulty that the daily variations there observed are markedly different from those in the majority of places, and it is probable that the nearness of London is fatal to any generally useful series of observations of atmospheric electricity being conducted in our national Observatory.

ON THE RECENT DEVELOPMENT OF THE SINGLE-ACTING HIGH-SPEED ENGINE FOR CENTRAL STATION WORK.*

BY MARK ROBINSON.

(*Concluded from page 122.*)

APPENDIX.

Description of the Willans Central-Valve Engine.—The engine is single-acting and on the "constant-thrust" principle—that is to say, the connecting rods are always in compression, never in tension. All the brasses are held close together, both upon the up-stroke and upon the down-stroke. The latter is the working or effective stroke; during the first portion of it the steam pressure in the pistons, of course, presses all parts against the cranks, and the crank shaft against the lower main-bearing brasses; in the later portion of the down-stroke the inertia of the parts, as they are brought to rest by the changing angle of the crank, also helps to keep them in compression. On the up-stroke, when no work is being done, and when the steam is being merely exhausted from the several cylinders, the inertia of the parts as they undergo acceleration by the crank also keeps them in compression for the earlier portion of the stroke; in the later portion they are cushioned by the arrangement to be afterwards described. The result is that in no part of the stroke, up or down, do the parts tend to separate; consequently there is total absence of "back

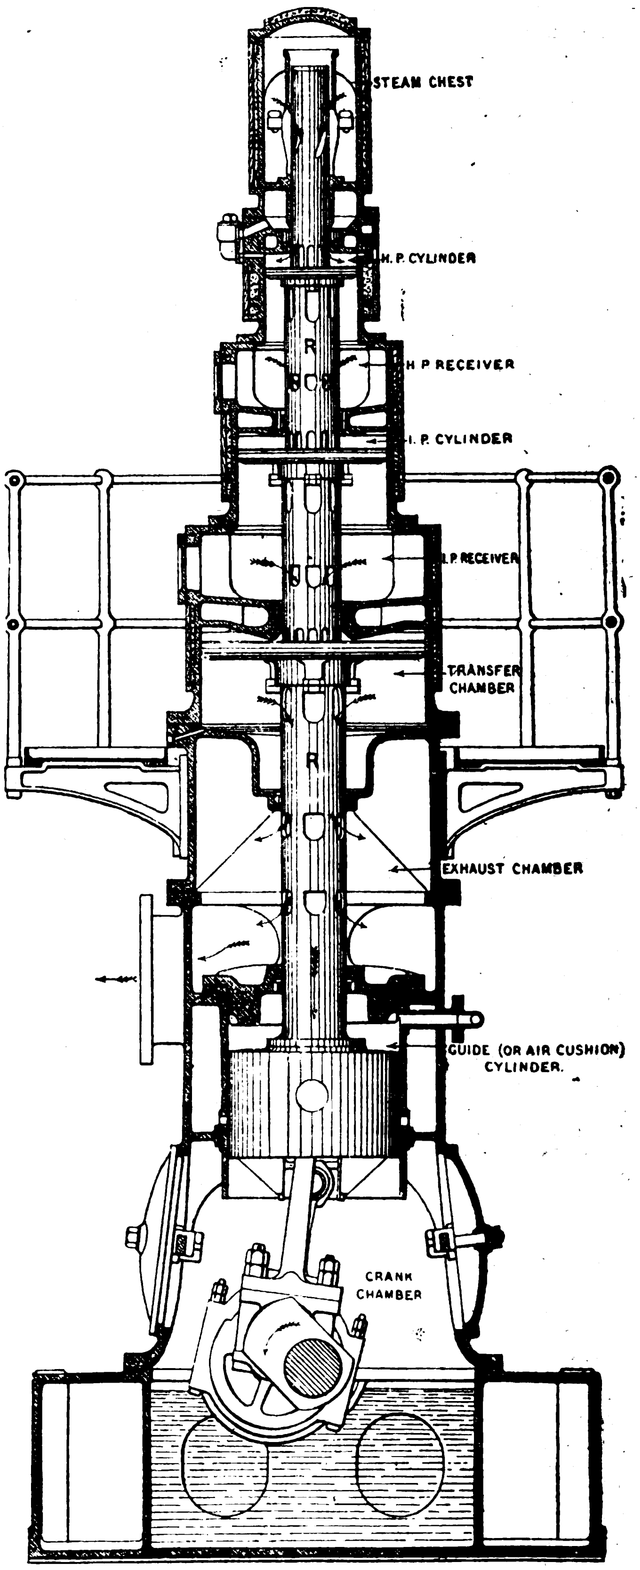

Fig. 15.

lash" or "lost motion," and "knock" cannot arise, as it would if the engine were double-acting, particularly in view of the high speed adopted.

Fig. 15 shows a triple-expansion condensing engine in section (through one line of cylinders). The steam is distributed throughout by the hollow piston-rod R (sometimes called the "trunk."). It enters from the steam chest by the oblique cut-off ports, shown

* Paper read before the Institution of Electrical Engineers

Digitized by Google

near the top of the piston rod. By the movement of the line of piston valves, which works inside the piston rod (driven by the eccentric shown), the steam passes into the high-pressure cylinder, at the beginning of the stroke, by the holes or ports shown just above the high-pressure piston. It is important to remember that this ring of ports is the only inlet to and outlet from the cylinder, and that it moves up and down with the piston. The action of the valve inside is shown in detail in Fig. 1, which represents it in the exhaust position.

The valve gives just the same steam distribution as an ordinary slide valve, with a slow cut-off at about three-quarter stroke, or a little later. Cut-off is, however, actually effected by the oblique ports in the steam chest, which, at a point in the stroke either pre-arranged in the design of the engine or controlled by the governor, pass behind rings, or a sleeve, so disposed as to prevent the further supply of steam for that revolution. As the cut-off motion is the same as that of the pistons themselves, the cut-off is very prompt, and shows a sharp corner in the diagram.

After the steam has worked expansively in the high-pressure cylinder, the valve passes above the ports (*see* Fig. 1), and opens communication from the working end of the cylinder—*i e.*, the space above the piston—to the space below it, which is called the high-pressure receiver, but which is equally a steam chest for the intermediate pressure or intermediate cylinder. During the up-stroke the steam is simply transferred from one side of the piston to the other; the whole cylinder, including the "working end," at that time forms part of the receiver.

When the next down-stroke commences, the steam in the high-pressure receiver is passed into the intermediate-pressure cylinder. It enters the hollow piston rod again from the receiver by the ring of short square-headed holes shown, and passes from the piston rod to the cylinder by the ring of ports shown just above the intermediate-pressure piston. Cut-off in this case is given by the square-headed ports passing into the gland in the intermediate-pressure cylinder-cover, and so losing the supply of steam from the high-pressure receiver (=intermediate-pressure steam-chest). The cycle is exactly the same as already described for the high-pressure cylinder, and at the end of the *second* revolution the steam fills the intermediate-pressure receiver. Thence, in the *third* revolution, it passes into the low-pressure cylinder; and in the second, or exhaust, half of that revolution, it passes from the low-pressure cylinder—*i.e.*, from its upper end to the lower end, of course without material change of volume or pressure. It is only during the first half of the *fourth* revolution that it finally passes away from the "transfer chamber" to the "exhaust chamber," the latter being in permanent communication with the condenser.

The full cycle thus described is that of a *triple-expansion Cornish engine*. In each separate stage of the expansion the complete Cornish cycle can be traced, and it is evidenced by two separate diagrams from the upper and lower end of each cylinder. The diagram from each receiver, or from the "transfer chamber," represents (as in every Cornish engine) work done upon the up-stroke, but it indirectly contributes to the power of the engine, for on the up-stroke the piston is in equilibrio, while the removal of back pressure on the down-stroke is a virtual addition to the size of the diagram from the upper end of the cylinder. The advantage is that the total range of temperature due to each stage of expansion does not take effect in the working cylinder, but only part of it. Part of the temperature range acts in the receiver only, where it does little harm; the limitation of the temperature range in the working cylinder is, of course, a clear gain in the matter of initial condensation. The adoption of the Cornish cycle in this engine is fully considered in the Paper in paragraph 16, *et seq.*

The construction of the pistons, and of the rings, which are very distinctive, is shown in Figs. 1 and 2, and is fully described in paragraph 12.

A complete line of valves (from a compound engine) is shown in Fig. 3.

The arrangements for self drainage from the cylinders are of great importance in the economy of the engine; they are explained fully in paragraphs 14 and 15.

All these points—viz., the special piston (and valve and gland) rings; the special arrangement for drainage; and the use of the "Cornish cycle"—are of great importance, and, except the last, are peculiar to the Willans engine, while all are peculiar to single-acting engines. They are described at length, and their advantages are pointed out, in the Paper, from paragraph 11 onwards. (Steam-packed rings can be applied in double-acting engines, but only by providing two complete sets of piston rings, with follower, &c., for each piston.)

The special glands (taking the place of stuffing boxes) are described and illustrated in paragraph 12.

The cushioning arrangement, before referred to, is special to the Willans engine. The guides take the formed of bored cylinders, and the crossheads are pistons, without rings. The top of the guide cylinder is closed, and on the up-stroke the air in it is compressed to the extent necessary to cushion the pistons and other parts. The power stored in the air by compression on the up-stroke is given out again during the immediately succeeding down-stroke, without sensible loss.

In a compound engine there are but two cylinders in series, but the "cycle" in each is precisely the same; in a simple engine only one. Sometimes the final "transfer chamber" is omitted (*see* paragraph 18), and the steam exhausts directly from the working (upper) end of the low-pressure cylinder into the condenser or atmosphere—*i.e.*, the lower end of the cylinder is in permanent connection with the exhaust.

The line of valves is driven by an eccentric *on the crank pin.* It is necessary that the source of motion for the valves should itself move up and down with the pistons, since the ports which have to be opened and closed also move up and down. There is an eccentric rod, which takes on to a hardened pin in a valve guide-piston; the latter works in a bored guide, formed inside the main guide-piston.

There are two connecting rods to each line of pistons, one on each side of the eccentric; the eccentric rod plays between them.

The cranks and all working parts, except the cylinders and valves, are lubricated by the splash of the cranks in the crank-chamber, where the lubricant usually consists of a mixture of oil and water. The guides and the pins at the upper ends of the connecting rods and eccentric rods are readily reached by the splash.

The cut-off in the first or high-pressure cylinder is effected, as before stated, by the movement of the ports in that part of the hollow piston-rod which projects into the steam chest. Where the engine has an invariable expansion, the cut-off ports, as they are called, are of the same shape as those for the succeeding cylinders, and they lose their supply of steam by merely passing into the gland which separates the high-pressure cylinder from the steam chest. If early cut-off is desired, the gland itself is raised a little by packing pieces between it and the cylinder top. In that case the ports enter the gland earlier, and cut-off is earlier.

Where the expansion is to be made variable, either by hand or by the governor, inclined ports are used, and the upper end of the piston rod is surrounded by a sleeve, which also has inclined ports in it. The sleeve is capable of a certain amount of rotation, which causes the ports in the rod to be covered (by the solid part of the sleeve) earlier or later. In the later patterns the sleeve is suspended by a spindle which passes through a gland in the top of the steam-chest, and the spindle is rotated by suitable links, &c. These are moved by hand, or by a relay cylinder, the action of which is controlled by the governor. The nature of the gear is more fully described in paragraph 52 of the Paper.

It will be noticed, in Fig. 15, that there is a hollow space in the casting under the bottom of each receiver. This is supplied with steam, and acts as a jacket, passing heat into the upper part of the working cylinder, and serving to re-evaporate, in the receiver, the the water which may enter it from the preceding cylinder. The later engines are without this jacket arrangement. Like all attempts to improve the Willans engine by jacketing, it has been unsuccessful. It reduces the consumption of steam in the cylinders per indicated horse-power, but the weight of steam condensed in the jackets just equals that which is saved in the cylinders. Apparently, a high-speed engine, *with good natural drainage* and ample sub-division of the total range of temperature, suffers too little from initial condensation to be capable of improvement by jacketing.

Speakers who have returned their proofs revised have their remarks prefaced by an asterisk.

DISCUSSION.

*The PRESIDENT (Mr. R. E. Crompton), after proposing a vote of thanks to Mr. Robinson, said he need hardly call attention to the extreme and paramount importance of this question of the development of the high-speed engine to those who were electrical engineers and power generators on a large scale. He thought their great progress dated from the time when Mr. Willans began to pay such close attention to the high-speed engine, and that fact should be the warrant for the Paper that had been read that evening. He hoped, after Mr. Robinson had acted in such a self-denying manner by cutting his Paper down to a mere abstract, that the discussion would be worthy of the Paper, and that they would be able to spend the remainder of that meeting and the whole of another in the discussion of it.

*Mr. J. S. RAWORTH said they had had a very great treat that night, because they had heard a gentleman read to them a Paper on a mechanical subject who was evidently not only a good engineer, but also a master of the literary art. He quite agreed with the President, that the electrical industry owed a very great deal to Mr. Willans for this wonderful engine, because it enabled electric lighting to be introduced in its early stages under circumstances in which, perhaps, no other engine could have existed. He did not, however, quite agree with the President in suggesting that electricity would not have advanced so rapidly but for this engine, although it was quite possible that it would not have advanced so rapidly within the confines of the London postal district but for the work which Mr. Willans had done, and of which he had given them the

Digitized by Google

benefit. While he (the speaker) did his work with other kinds of engines, he must say he was a great admirer of enclosed engines, and he did not think all the advantages claimed by Mr. Robinson for the Willans engine came from the fact that it was a single-acting engine, but accrued from the fact that it was an enclosed engine. They had at the top of the Paper the title, "The Recent Development of the Single-acting High-speed Engine for Central Station Work," and he rather imagined that when Mr. Robinson took that title he was going to give them a history of the development of the single-acting engine; but the Paper itself was confined, so far as he understood it, to the recent developments of the Willans engine, and the author had not thought fit to go back to the early history of the Willans engine, because there were many single-acting engines before the Willans engine, and even the Willans engine itself went as far back as 1874. He did not want to develop that point, but to direct attention to the second paragraph, in which Mr. Robinson said that a certain Paper stated that if they "had stuck to the builders of mill engines and marine engines, instead of trying to strike out a new line of steam engines for themselves, electric lighting would have been very much the gainer." He (the speaker) quite agreed that that was all nonsense. The author said, further down, that the total indicated horse-power installed in all the lighting stations in Great Britain was 101,390, and of this his firm had made 53,340. Well, the Brush Company had built 31,000, so there were only about 17,000 left. He did not know whether either of them was exaggerating, but he would take it for the moment that both were speaking the truth. This fact remained, they had not been greatly indebted to mill engineers. He would undertake to say that there was no one in that room engaged in this industry who had not at one time or another tried the effect of consulting one of those engine builders. His experience had been that they failed entirely to grasp the situation. They knew how to design a good mill engine, but it was quite another thing to turn out an engine to drive an electric dynamo, which responded to every touch and reproduced the fluctuations of the governor with absolute accuracy, and which had not got the steadying influence of 200 H.P. or 300 H.P. in mill shafting. He had no hesitation in saying that if the horizontal engine lasted 40 years the beam engine would last 80 years, and if corporations, desiring to save a few pence or pounds in repairs, did not mind spending a good many more pounds in interest on money and depreciation, by all means let them put in a beam engine instead of a horizontal, and get one to last to all eternity. Coming back to the Willans engine, he was, as he had said, a very great admirer of that contrivance; he thought it had extremely good points about it. He had used some with very great success. Mr. Robinson had put its features most admirably, giving them some idea as to its engineering construction and the theory followed out by its makers, of which some were entirely ignorant before. This ingenious engine had one difficulty, and engineers would look on it as a serious difficulty; that was that it was a Chinese puzzle, and they could not afford always to keep a Japanese on the premises to solve the problem. When he said it was a Chinese puzzle, he meant that they could not take out any one portion to see whether that part was in proper order or not. Now he wanted to take them for one moment to the question of high speed. Mr. Robinson seemed to think that the speed of revolution was a natural corollary from having the thrust entirely in one direction, and he found that a great many people were carried away by the same specious argument. He would ask them to consider that a Willans engine giving 360 I.H.P. had only a stroke of 9in. Now did anybody ever see a double-acting engine with anything like so small a stroke for that high power? In his experience there never was such an engine, and the reason was obvious. The double-acting engine if run for a few minutes might get an appreciable amount of wear and slack. They knew that a small amount of knock would make a large noise. A small drummer boy would awaken a whole village. He noticed with considerable satisfaction that Mr. Robinson admitted that for the extremest speeds they must use a double-acting engine. The reason was obvious, because on the back stroke they had to put velocity into the working parts out of the cranks and not out of the steam, and the strain would become excessive. Now they found the question of wear discussed, and he was sorry to say he could not quite agree with the author; in clause 7 he said, "It is evident that a single-acting engine in which there is absolutely no back-lash and no reversal of stresses, and which is otherwise rightly proportioned, will run freer from wear in its brasses than a double-acting engine at any but very moderate speeds." He was quite willing to admit that the Willans engine was pretty free from wear, but he did not attribute it to that cause. He had had large experience with bearings run with considerable weights acting entirely in one direction. The Mordey Victoria alternator had a magnet which weighed a considerable number of tons, and it was always a very great difficulty to get the bearings of that machine to run at all. At the high speed of the old belt-driven machines it was found difficult to get it to run unless they adopted forced lubrication. By changing over the strains when the engine piston passed the ends of the stroke a gap was made into which the oil could freely enter, and it gave them the opportunity of getting better lubrication than they could get with constant pressure in one direction. He asserted that any ordinary Tangye engine would give from 90 per cent. upwards in brake efficiency. When they came to the slow-running horizontal engines which were so much admired, he quite admitted they could not do it because they had to drag forwards and backwards on a long rail with no wheels a heavy piston only imperfectly lubricated. This it was that reduced the brake efficiency of the horizontal engine. He heartily agreed that electrical engineers were greatly indebted to Messrs. Willans and Robinson for the specially highly-developed machines which they had put in their hands for getting over the difficulties of many very awkward conditions.

Mr. H. G. BOOTH said there were one or two remarks he would like to make, and particularly one with reference to the Cornish cycle. The author referred in the Paper to the overlapping of the temperature ranges in the cylinders of an ordinary engine, stating that that was not the case with the Willans engine. He did not think that was altogether correct. He had a diagram in which the expansion curve was taken right forward. The exhaust line went backwards almost like the diagram Mr. Robinson had given them. If the low pressure of that engine were as he had pointed out, there was no overlapping of the range of temperature in an ordinary combined engine which was properly designed, and the valves of which were properly set. That was a point which ought rather to be insisted upon. He admitted the value of the Cornish cycle, but thought the ordinary compound engine got the same result.

* Mr. E. TREMLETT CARTER said that the initial cylinder condensation depended on the temperature ranges of any mass particle of the iron. What Mr. Robinson had shown was that in the Cornish cycle the fluctuation of the temperature of the steam in the cylinder was divided into two; but the fluctuation of the temperature of any particle of the cylinder liner was not divided into two, but was really continuous, as if the whole expansion took place in one stage. While one side of the piston underwent the fluctuation of temperature represented by the upper portion of Fig. 6, when it had passed over on to the other side of the piston, it became now the other side of the cylinder, and underwent the fluctuation of temperature represented by the lower part of the diagram. His point was that the two stages of the fluctuation of temperature did not take place in two separate cylinders with two separate surfaces, but in one cylinder and with one surface. Every particle of iron underwent two changes of temperature, and the variation of temperature of the liner caused the condensation of water on the surface just the same whether they had a Cornish cycle or whether they had an ordinary expansion in one stage and on only one side of the piston.

*Col. SALE spoke as to the relative cost of these methods of driving. Recently he had had occasion to call for tenders on the part of the Government for certain engines and dynamos to turn out 500 H.P., the dynamos to be direct driven. The question lay between slow-speed engines and flywheel armatures and a comparatively quick-speed engine driving a multipolar dynamo, and a high-speed engine driving a comparatively small dynamo with comparatively high speed. The low-speed engine ran at 80, and the speed of the dynamos was 120. The speed of the high-speed engine was not specified. It would be supposed that far and away the cheapest would be the high-speed engine and dynamo—both comparatively small—but that was not the case. The highest price, but not much the highest price, was that of the slow-speed engine and the flywheel armature. Next in order came the high-speed engine and the high-speed dynamo together. The lowest priced of all was the vertical engine and the multipolar dynamo, running at 120. This result was contrary to expectation.

THURSDAY, MAY 23RD.

*Mr. ALEXANDER SIEMENS said it was a singular coincidence that that day was the anniversary of Mr. Willans' death. He should not have risen to occupy their time if Mr. Robinson had not mentioned his Newcastle Paper. With regard to the figures given in that Paper he would remind them that they were not test figures for show-trials, but they were the results obtained in the regular working of their central station in Woolwich. As to the results obtained by the Belliss engine, he would specially observe that that engine was the very first of its kind made by Messrs. Belliss, and it was only natural that later engines should show better results than the one about which he reported at Newcastle.

*Mr. CHANDLER said there were one or two points in Mr. Robinson's Paper with which he could not quite agree. Firstly, he told them the valve rings were "not steam packed;" that was the slide valve rings. Now, if they were not steam packed what prevented them from collapsing during the transit past the portholes in the trunk? Then, again, they were told that steam was admitted to the space behind the piston rings, and this steam, assisted by the thin junk ring or follower, kept the rings in constant thrust downwards. But the same conditions were arrived at with an old-fashioned piston. He simply mentioned this to show that not only could the most modern engine accomplish these things, but also the most ancient.

*Mr. MORCOM said he was rather at a loss as to the manner of his reply to Mr. Robinson's Paper, as he had referred so extremely politely to the Belliss engine in three or four points, but it had, however, been pointed out to him that the whole tenor of the Paper was to condemn this engine quite as much as any of the other engines to which Mr. Robinson had been referring. Now, he might say at once they had proved certainly that in all the points to which Mr. Robinson had referred they had an engine at least as good as the Willans. He would prove his words further on; but it would be useful to deal with the matter historically in the same way as Mr. Robinson had done, and show why their engine was designed. They had been building high-speed engines running up to quite as high revolutions as the present electric lighting engine, 500 and thereabout, for all kinds of powers, for a matter of nearly 30 years, so they knew what a double-acting engine could do, and what it could not do. When they were brought face to face with the necessity of devising an engine that would run continuously for station work at the higher speed of revolution, they naturally looked to the single-acting engine as a possible means out of the difficulty. They were building then for the Navy, and their first view was naturally in that direction. The engines for electrical purposes in the Navy some years ago were nearly altogether single-acting engines; but the Admiralty, owing to the difficulties occurring with the single-acting engine, permitted double-acting engines to be employed at the same time, but would not permit them to run at much more than half the number of revolutions. Gradually representations were made as to most serious collapses of the Willans engine, lines of valves coming down, crank shafts breaking, and pistons smashing altogether. In consequence at

Digitized by Google

the present time the Admiralty, and also a number of other Governments, would not have a single-acting engine for driving the electric light. Double-acting engines had been going through the same duties alongside of them, and had not shown the collapses and difficulties. The reason was easily seen by taking the single-acting engine as it stood as compared with the double-acting engine. There was always the fact that you had twice the area of the piston; that meant double the strain upon each rod, double the pressure on every bearing, and therefore, under ordinary circumstances, double the wear. In addition to this, the mode in which the pressure was taken, *i.e.*, the constant thrust which Mr. Robinson had referred to as being a favourable feature in the engine, was bad. This constant thrust had been a thing he had had some experience with in the oil-testing machinery at one of the dockyards, when the apparatus had to be converted from single to double acting to enable it to run at all. These facts helped them to go boldly into the design of a double-acting engine, knowing that they were going to get somewhere near if not up to the Willans engine. He would now take up the points Mr. Robinson had referred to one by one and see how they fared. First came the question of economy. He had there the results of a trial of one of a set of engines for St. Pancras, recently made under conditions very parallel with those obtained at Thames Ditton; in fact, they had copied their testing arrangements as exactly as they knew how to do. The tests were made in the presence of Prof. Robinson's assistants, and were carefully checked. There were, in fact, three engines of the sort, and a comparison between the three showed that the results were practically correct as they stood. They had there certainly as good an engine as they could make at the present time. It showed that with pressure of steam about 120lb. the water per electrical horse-power had come out to a mean of 19·89 for an average of six hours, running under full power. The power that they ran the engine at was about 10 per cent. higher than the maximum required at the station, an extra full power being required occasionally. As the slide valves were set for that, they preferred to run at that power to get the best possible result. That result was as good as the Willans engine could do with that pressure of steam. The efficiency of the engine came out at 92, the higher figure which Mr. Robinson had spoken about. There was no doubt about this fact: that there was not a halfpenny between the two engines so far as economy went, and they might take his word for it that there was at present no use paying any more for it. As far as durability went, Mr. Siemens had referred to the engine that was spoken about at Newcastle. That, of course, was one of their first engines; he wished, seeing the position it was in, that it was one of their last ones. He had seen that engine opened up, and after the two years' hard running there was no wear whatever on the brasses, and no necessity for adjustment. He could also refer to many other cases, where after long continuous running the forced system of lubrication had entirely prevented wear of the working parts. Mr. Robinson put his finger on the reason why their (Messrs. Belliss') engine showed up so much better on the lower loads, but that question of piston ring friction was a big question, and was going to be a bigger one by-and-by. At the present time superheating was largely in the air, and he thought he should be willing as an engineer to predict that in the next year or two superheating would be very largely in electric lighting stations. If superheating came in, the question of rings and the friction they might have would be a much more important thing than it was now. The necessity for lubrication would also be of more importance, and there would also be the necessity for keeping that lubrication out of the boilers. With condensing and superheating the Willans engine would therefore stand a still worse chance. As far as governing went, one would say off-hand that the double-acting engine ought, having two impulses in the revolution, to be better than the single-acting engine for governing. He had seen some single acting engines where it had been necessary to throw the governors out and govern the station by means of a man at the throttle. If Mr. A. H. Preece were here he could corroborate the fact of the excellent working of the new type of throttle governor he had seen on an engine at their works last week. With this the governing was practically isochronous, and the sudden run up when all the load was thrown off only averaged about 2 per cent.

*Mr. ARTHUR WRIGHT, who was called upon by the Chairman, said he was afraid his remarks would be uninteresting, as he had nothing but compliments to offer. He had had about 2,000 H.P. of these engines under his control and had had no bad experience whatever. The whole of that 2,000 H.P. was managed by two men and a boy. He had hardly ever seen the insides of the engines, and had had no bother with them of any kind. Results showed that, so far as economy was concerned, they at Brighton could achieve it as well as other people. He could not imagine a better engine.

*Mr. DRUITT HALPIN said at the last meeting they heard some very high figures indeed about brake efficiency. He had never had one of these single-acting enclosed engines on the brake and knew nothing at all about their efficiency. But they heard a good deal about the "common or garden" engines running into fabulous efficiency—91, 92, and 94 per cent. —and he certainly could not believe any figures of that kind unless he was given means of verifying the statements. Of course, they knew there was nothing that would lie more consistently than an indicator, except, of course, a voltmeter and an ammeter. It was also known that it was very usual to get wrong indications in the brake. The remarks of the last speaker about the oiling and the necessity of having reversal of stress at the end of the stroke, change of stress, to enable the engine to run, reminded him of a discussion he had with the late Director-General of the Belgian Railways. His view was that all railway travelling would be impossible merely from the point of view of lubrication if it were not for the slight tremors produced by the road allowing the lubrication to get in: else the whole thing would stop and no system of lubrication could be maintained. But he certainly could not agree with the last speaker that it was necessary to have this perfect reversal of stress to get lubrication in.

*Mr. GEIPEL said the Paper which Mr. Robinson had put before them bristled with information and points which were of the utmost interest. There were one or two points in the Paper, however, to which he would refer, with a view to obtaining even more information from the author than he had already given. In the first place, in speaking of the costliness of slow-speed direct-driven steam dynamos, he took it that Mr. Robinson referred only to first cost; otherwise, was it not somewhat previous to state that high-speed would last as long as slow-speed engines? They knew that there were slow-speed engines which had been at work for 42 years and upwards which were running at the present day; that the Willans or any other high-speed engine would do this had yet to be proved. If they would not last so long then it was necessary to take into consideration whether the earlier renewal of the one would balance the increased first cost of the other. Mr. Robinson referred to the difficulty of overcoming the vibration so far as concerned the one and two-crank engines, and recommended the three-crank double engine. This, of course, was not a question which greatly concerned the users of high-tension systems, who could generally put their engines in distant places where vibration was of little moment. But was not the method of overcoming the vibration advocated, namely the use of double engines each having 9 cylinder or 18 cylinders in all, a further argument in favour of the use of slow-speed for the day-load engines? For tramway work the author correctly emphasised the necessity of engines considerably larger than were required for the mean power, and, in paragraph 23, he referred to the higher mechanical efficiency of double-acting engines at light loads. He agreed with the author in that, and believed that for such work the double-acting engine was best, at least in that respect. The necessity of using powerful governors, and giving them next to nothing to do, mentioned in paragraph 49, could not be too strenuously dwelt on. The makers of throttle-valve governors were too prone to cut down the weight of the balls. There was no part in an electric light engine which was more important, and to which probably less attention had been paid hitherto, than the governor. He agreed with the author as to the desirability of using plenty of flywheel power to control the engine in the event of sudden variations in the load, though he did not believe that the flywheel had so much steadying effect on the governor as he stated. The great sensitiveness of shaft governors was, in his opinion, partly attributable to a continual variation in the strains on the parts controlled by the balls; anyhow, speaking from experience, he had found shaft governors, notwithstanding the heavy work entailed on the balls, to give closer governing than throttle-valve governors.

*Mr. J. N. SHOOLBRED said there were one or two points he would like to remark upon. There was one point in regard to which he was afraid he could not eulogise the engine in the same way that Mr. Wright had done. It seemed to him to be a blemish on the Willans engine—the use of the throttle valve. To use it economically it was necessary to keep it pretty fully loaded, and it had not the advantage of the other engine in respect to the expansion valve; and it seemed rather contrary to one's ordinary ideas, that the steam at a very high pressure should be demanded, only to be throttled down and made use of at a loss of 25 per cent., or perhaps even 75 per cent., of its pressure. That in itself seemed an anomaly. The Willans engine was spoken of as the engine of the future; he would rather look at it as the engine of the present. He thought as they got into larger powers the more would the double-acting engine be used, even more than the Willans.

*Mr. R. W. ALLEN said, as a designer of double-acting engines for some years, he would like to give Messrs. Willans and Robinson credit for setting them a lead, not only in the designs of double-acting engines, but also in the excellence of manufacture, which was a most important point. He would lay stress on the crank shaft, which was the basis of an engine. There were very few men who could really turn a crank shaft which was true; and unless the crank shaft pin was true, trouble would certainly take place. Moreover it is impossible to obtain the high efficiency which is shown in the paper unless the greatest care is taken in the manufacture of every part. With regard to what Mr. Morcom had said, no doubt when he designed his engine, like his firm themselves had done with theirs, he had had the section of a Willans engine in front of him, and had taken advantage of the 15 years' experience of Messrs. Willans and Robinson, which had not only helped them, but the world at large, the designers of small and large engines. No doubt what Mr. Morcom had said was true with regard to the engines in the Navy, but that was, of course, due to circumstances over which Messrs. Willans and Robinson had no control. He could give an instance of the way in which one of his firm's double-acting engines had been treated on a ship which had been lying up in port

Digitized by Google

for a few days. Water had accumulated in the steam pipe, and the engines were working at full load; this was the night before sailing. The engineers turned on the wrong cock, and instead of the water going to the condenser it came right back to the engine, and the engines were doubled up. That would take place with a single-acting engine just the same as with a double-acting engine.

Mr. R. DUMAS said although he had had nothing to do with central station lighting, he had had a little to do with the Willans engines on board her Majesty's ships, and as far as his experience was concerned he did not see that the interchangeable system of manufacture pursued at the Willans' works was found to be a very great advantage. There were, however, some points to which he should like to call attention, and in regard to which he would ask for further information. With reference to the piston rings it was rather surprising to find that steam packing had been so successful, since it had been tried and abandoned by so many others; the only conclusion one could come to was that some essential point had been overlooked in previous designs. With the piston rings exposed to the varying pressure of steam in the cylinder it might be expected in cases where the lubrication was not efficient that the wear in the upper part of the cylinder would exceed the wear in the lower part. With regard to the piston valve packing it would be interesting to know if any experiments had been made with a view to ascertaining the steam pressure in the interior of the valve; probably it was not far from a mean between the initial and exhaust pressures. Assuming this to be the case it seemed evident that collapsing of the rings of the upper part of the valve must take place in consequence of the excess of the outside pressure, and this especially when the packing rings came opposite the ports. The lower rings, on the contrary, must be pressed somewhat severely against the valve trunk, as with them the inside pressure exceeded the outside. Probably, therefore, the wear in the lower part of the valve trunk was greater than in the upper part. Doubtless, Mr. Robinson's experience was sufficient to set this point at rest. He supposed the reason why no attempt had been made to subdivide the hollow valve was that the weight would be increased thereby, and this would increase the difficulties mentioned in the Paper in the case of throttling engines working on light loads. With regard to the internal drainage, the coning of the pistons was at once a simple and efficient way of overcoming the difficulty as far as the cylinders were concerned, and it was a most happy coincidence that the strength of the pistons was increased at the same time. With regard to the Cornish cycle, he was of opinion that that was a most important and beneficial feature in the engine. He was rather surprised to hear Mr. Tremlett Carter question its advantages. With regard to the air-cushioning arrangement, he understood that this was so designed as to keep the lines of parts (of course, excepting the line of valves) in constant thrust even when there was practically no pressure in the steam chest. This being so, it was clear that whatever effective pressure there was in the cylinders was added to the pressure due to the air cushion, and that the pressure on the crank pin must be very severe during some parts of the down stroke. Since there was so little clearance, and consequently compression, in a Willans engine, the valve trunk must for some parts of the up-stroke be in tension. He would like to know if there had been any trouble with breakages through the bottom row of ports. Doubtless the air-cushioning arrangement was very efficient and was more easily adjusted than the compression in a steam cylinder. In a double-acting engine the compression curve was often very deceptive, especially when the diagrams from the two ends of the cylinder were separated. Now that variable expansion had in some cases been adopted, and that the full pressure was available on the high-pressure piston for acceleration of the parts, there seemed to be no reason why an effort should not be made to get rid of the air-cushioning cylinder. This could be done by arranging for the valve itself to cut off about 0·6 of the stroke, release to take place at 0·9 and compression about 0·83. Naturally, the clearance volume and consequently surface would have to be increased; if it was objected that this would prejudicially affect the economy of the engine he would ask, what had been the effect of letting steam to the back of the piston rings, and thus considerably to increase the clearance surface? He was of opinion that the mechanical efficiency of the engine would be sensibly increased if the cushioning cylinder could be dispensed with. He was aware that this would not be possible if a late cut-off were required, as sufficient compression could not be obtained in the steam cylinder.

Mr. JEREMIAH HEAD said he had not had the opportunity of reading the Paper, and he was not a member of the Institution; but the President and Council had been kind enough to invite him to speak. The only point which had struck him in the exceedingly interesting discussion which had taken place was that raised by Mr. Morcom about the difference of the lubrication between a single acting and a double-acting engine. It might be of some slight interest to the meeting to know that a good many years ago he was so smitten with that beautiful piece of mechanism, the Brotherhood engine, that he determined to have one made that should be larger than any that had ever been made before. Accordingly he had one made for 20 H.P. to work with a pressure of 60lb. to the square inch above the atmosphere. This engine was put to drive a rolling mill, and it ran at 300 revolutions per minute; but he was sorry to say that it utterly failed in the end by the seizing of the crank pin. Very elaborate arrangements were made for oiling that crank pin; but the oil was not pumped in, it was merely allowed to run down the vertical piston rod and connecting rod with a considerable hydraulic head upon it. As he had said, it failed because the connecting rod ends continually seized the crank pin and pulled the engine out. That impressed him very strongly with the view that single-acting engines, which were always bearing on the journal in that way, were liable to fail unless some arrangement was made by which the oil could be pumped in at a pressure at least equal to that of the connecting rod on the crank pin. He thought that little bit of information might be considered to bear on the subject and be of interest to the meeting.

*The PRESIDENT said in bringing the discussion to a close he wished to say a few words, because he had had the honour and pleasure of being a very intimate friend of the late Mr. Willans. It was 19 years since he first bought a Willans engine, and he had been using Willans engines during the whole period of time which had since elapsed. After alluding to the attack which had been made by one technical journal, the President went on to say that he had had over 25 years' experience in direct charge of steam engines, and of the earlier part of that time he had very unpleasant recollections. He was then out in India, and had to put the brasses together himself very frequently, because native labour had to be taught; and he of all men could appreciate the difficulty of keeping double-acting engines in order, in eliminating troubles connected with the bearings, and in keeping the engines free from knocking and vibration. It was his strong feelings on that point which brought him in very early association, first with Mr. Brotherhood, whose name had not been sufficiently mentioned in this discussion, and subsequently with Mr. Willans. He was sure the firm of Willans and Robinson would be the first to acknowledge the great services which Mr. Brotherhood had rendered to the cause of high-speed engines. He would not touch those points in the discussion, which would be dealt with most completely by Mr. Robinson. He (the President) did not speak at all as an advocate of the Willans engine *quâ* Willans engine, but he did speak of it from the point of view of regarding it as a highly successful high-speed engine, and he did so because high-speed had been the making of electrical engineers, for if high-speed engines had not been introduced they would not have made such progress with their central station work as they had done. He thought Mr. Morcom and Mr. Chandler would agree with him in what he had said on that point: that the great trade that had been made and was likely yet to be made in high-speed engines owed a very great deal to the Thames Ditton firm. Mr. Raworth, in his very humorous speech, objected to the Willans engine because it was such a puzzle to put together. He (the President) must say that he did not understand this statement. He was in charge of a great many of these engines, and had always found that they were taken down and put together by labour much more unskilled than that usually employed in such cases, by men who were not fitters in the usual sense of the word, and who would not be trusted to fit together the brasses and other work of that kind in an ordinary double-acting engine. The reason was that in the Willans engine all they had to do was to take it to pieces and put it together again in just the same way, and if the parts were worn to put in others of the same kind. The work was perfectly simple and the men had only to obey orders. Mr. Raworth told them a most interesting story about a dynamo, a tramcar, and a horse. In his comparison between the complication of the motor of a tramcar and the inside of a horse he hit upon the real reason why many engineers, including himself, thought that Mr. Willans and other engineers who enclosed their engines had done the right thing. What mattered it that parts were complicated if it was found in practice that they were very effective and did not become deranged? The constructor of the horse was well aware of this: he knew the horse was as simple a machine as could be devised for the purpose, but knew also that people would object to see the working parts, and also knew that the lubrication and things of that sort were not nice things to be flying about in public, and therefore he encased them. He thought that was a sufficient justification for enclosing engines. They were flooded with leading articles in the technical journals to the effect that they (electrical engineers) ought to take lessons from the fountain-head, *i.e.*, the Lancashire mill engineer, in reference to engines. He had challenged all the fountain-head men to come there, and he could not get any of them to speak. Apparently they had nothing to say, or they would back up the articles that had been brought forward. But there could be no doubt that their outcry had influenced—and he regretted it very much—a number of the members of their profession, for engines were still being put in in a way which was really pandering to this outcry. This, he was sure, would be a cause of regret to the users of those engines when they compared their results with the results obtained by those who used high-speed engines in their central stations. He believed all the speakers that evening were in agreement on that point. He regretted that they had not some of the enemy present there that evening. No doubts were so frequently raised as those regarding the durability and the high cost of repairs of high-speed engines. Eight or nine years ago it was found that in central station work the cost of repairs was as little for high-speed engines as for low-speed, and in some cases it was even lower. They were getting rather tired of hearing these objections, and he would like to hear something fresh; he would like to hear upon what grounds those assertions were being made. He regetted to hear one gentleman speaking of sweeping up the interior of an engine in a dust-pan; he did not think that was a nice way of putting it. No doubt such things had been, and it was not to be wondered at, seeing the brutal way in which engines were treated in the Royal Navy, where they injected steam pipes full of water suddenly into the cylinders of the engine. It was far better that something should give way, and that a nasty accident should not take place. But there was very little doubt that such accidents did not occur now; any engineer who allowed them to occur in his station would not confess it, because he would know his experience was so abnormal that he would rather not be thought of as the extremely careless man he would prove himself to be by permitting such accidents. He did think they had every reason to be extremely proud of what the Thames Ditton firm, and of what Messrs. Belliss and Chandler, and other makers of high-speed engines, had done for them. They had enabled them to show figures—steam into electrical units—which were better than any other figures he had come across. The improvements in engine construction had been a very great movement in advance for the benefit of engineering generally, and for electrical engineering in particular, and for that reason he was extremely pleased that the last Paper of the session was upon so interesting a subject.

Digitized by Google

Mr. ROBINSON, in replying, said Mr. Raworth rather suggested that he must have treated of other single-acting engines than the Willans. The answer to that was to be found in the title of the Paper, which was "*Recent* Developments in High-Speed Engines." He had confined himself to improvements in the Willans engine, carried out either shortly before or shortly after Mr. Willans' death. If he had dealt with no other engines it was because none had taken, so far as he knew, a prominent part in central station work. In America there was the Westinghouse, of course, but he had not thought it necessary to deal with that. He had tried to make the Paper as general as he could. It would be but affectation to ignore the fact that the single-acting engine was for the present the Willans engine, and in that fact lay the chief reason why he was speaking to them upon the subject. As regards the amount of the total horse-power, he knew how difficult it was to get such figures. He had taken a public list, which excluded a large unfinished station, probably knocking a great deal off the Brush figures, and he had also excluded many thousands of horse-power which did not in his judgment come under the head of central station work for public lighting. Mr. Raworth had said the engine was such a Chinese puzzle, and that it was all boxed in. He (the speaker) never could sufficiently admire the virtuous disapproval of many engineers of parts which were boxed in. He was afraid he had not been sufficiently clear about engines for high-speed continuous working and constant thrust. Constant thrust enabled them to run an engine with no knock and very little wear, even at high speeds. They had had some difficulty with bearings apparently quite lightly loaded, where the shafts had formed part of a magnetic circuit, and the conclusion they came to was that such a bearing might appear to be lightly loaded, and yet for some magnetic reason might be very heavily loaded. Mr. Raworth had given himself and his colleagues credit for recent improvements. But those improvements had either been planned by Mr. Willans, or based upon experiments which he planned and carried out, the only exception being the automatic expansion gear now used. Mr. Morcom had shifted the discussion very much into the nature of a duel between single-acting and double-acting engines, and that was fair enough, because the Paper was in praise of that principle. Mr. Morcom said his firm had made engines running at very high speeds for more than 30 years. He presumed that was for marine purposes. [Mr. MORCOM: The large majority have been marine engines, large yacht engines, pinnace engines, and so on.] He was afraid that he had caused some indignation at the Admiralty by telling them that the Willans engine was intended to be used as a steam engine and not as a hydraulic engine. Mr. Morcom said there must, of course, be a double area of piston and cooling surface, and double stresses on the pins in the single-acting in comparison with the double-acting engine. That, of course, was true if they were to run at the same speed. That was the crux of the whole question. They (his firm) said you could not run permanently and continuously at the same speed. That was a point to be threshed out between the two systems. Mr. Morcom thought constant thrust was no good. He attached importance to the play of the crank-pin in its brasses or the shaft in its brasses, letting oil in underneath. No doubt the double-acting engine had advantages in that respect; but they had turned out something like 100,000 H.P. of Willans engines, and had been almost absolutely free from trouble with their main bearings, which were most pressed down on the brasses. Mr. Morcom referred also to economy. The economy in the St. Pancras figures was very great, but he did not think it was quite correct to say they were the same as some of the figures that could be given for single-acting engines. Still, it was a very good economy and a very good efficiency. All he could say was that, through the uncertainty of measurements, and especially in commercial engine rooms, they were always a little shy of quoting extreme figures. The highest of the efficiencies given, he thought, just about corresponded with what had been occasionally obtained at Thames Ditton. With regard to governing, he would just remark that the double-acting engine with two cranks only was in the same position as a single-acting engine with two cranks as regards impulses per minute, because two were coming at the same time. Governing was of no importance in this connection. Mr. Geipel asked how long the engines would last; would they last 42 years? It would take nearly 30 years to answer that question. So far as the shells went he did not see why they should not. As to vibration, he had never advocated six-crank engines for lighting stations, or for tramway work, except where absolute absence of vibration was to be obtained. That subject was gone into purely for marine purposes, and it was satisfactory to know that they had found something to get over vibration so slight that most people would describe it as no vibration at all. Far more importance attached to the question of vibration on board ship than in a lighting station. If they worked at very light load they certainly had to throttle the load down lamentably low; but experiments show that if they got down to very low load indeed the throttled engine was absolutely more economical than the cut-off, and that at moderately light loads the difference between them was extremely small. Seeing what the throttle or valve-expansion engine would achieve at full load, the moral was that they should not work at light loads at all; but if they must do so, as little as possible. Mr. Dumas supposed steam-packing had been tried before, but he (the speaker) thought not on the single-acting engine; that was to say, steam-packed rings were not worked in any way under the same conditions as in the single-acting engines. Mr. Dumas also asked if there were more wear at the top than at the bottom. He did not think so; it was quite equal at both ends. Mr. Dumas said the trunk must be in tension sometimes. He could assure them it would come to grief if it were. He greatly lamented that they had not had the criticisms of some of the advocates of slow-running. He wished they would come forward and give it hot to the fast-running engines. Mr. Morcom he was obliged to look on more as an ally than as an opponent, for he was a high-speed man. He thanked them all very sincerely for the kind way in which they had received the Paper.

PHYSICAL SOCIETY.

At an ordinary meeting of this Society, held on May 24, 1895, Capt. W. de W. Abney (President) in the chair,

Mr. BURSTALL commenced the reading of a Paper

"On the Measurement of a Cyclically Varying Temperature."

The experiments were undertaken with a view of measuring the temperature inside the cylinder of a gas engine at different points of the stroke of the piston. A modified form of platinum thermometer is employed to measure the temperature, and since the variations in temperature are extremely rapid, the wire had to be very thin and unprotected by any covering such as is ordinarily employed. The leads of the thermometer pass through a slate plug fixed in a seamless steel tube, asbestos being used as a packing to prevent leakage. The resistance of the thermometer was measured by means of a Wheatstone's bridge. Since the temperature at a certain part only of the *working* stroke had to be measured, and the galvanometer circuit was broken in two places, one of these breaks was closed by means of a cam on the shaft of the engine at a given point of each revolution, while the other was closed when an explosion took place by means of a relay worked by the pointer of a steam-engine indicator attached to the cylinder of the engine. The remainder of the Paper was postponed till the next meeting.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

FRIDAY, June 7th.

ROYAL INSTITUTION.

9 p.m. Friday Evening Discourse: "Phénomènes Physique des Hautes Régions de l'Atmosphère," by Prof. Alfred Cornu, F.R.S.

Australasian Electric Light and Power Wire Regulations.—We have received from Sir Charles Todd, the Postmaster-General and Superintendent of Telegraphs for South Australia, a copy of the second report of the Committee appointed at the Postal and Telegraph Conference, held at Hobart in 1892, for the purpose of drawing up a set of regulations with regard to electric light and power circuits. The report is dated Melbourne, November 8, 1894, and is signed by Sir Charles Todd, Major P. Walker, and Messrs. G. Smibert, R. Henry, Oswald Haes, A. J. Arnot, and J. O. Callender. The report states that it is the opinion of the Committee that it is desirable that the laws and regulations relating to electric light and power wires should, as far as possible, be uniform throughout Australasia. The regulations suggested by the Committee are a faithful copy of the (latest pattern but one) Board of Trade regulations dealing with the same subject, the main point of difference being, perhaps, that lightning arresters are specified where no mention of them is made in our English rules. The much-discussed regulation with regard to the thickness of the insulation of overhead wires is adopted as it stands in the Board of Trade rules; a minimum section for overhead wires is also specified, and suspension from a bearer wire is not absolutely obligatory. There are also one or two regulations dealing with transformers attached to street poles. In the electric traction regulations the minimum height of the trolley wire above the ground is put at 18ft. and guard wires are specified. Whilst Board of Trade regulations require an uninsulated return to be connected to the rails at every 100ft., the suggested regulations in Australasia propose to connect at each length of rail. Major Cardew's much-discussed suggestion of testing leakage to pipes by interposing a battery of three Leclanché cells is adopted without alteration. The Board of Trade regulations with regard to maximum leakage current, minimum insulation of underground cables, &c., are also all incorporated in the suggested Australian rules.

The Electrician.

(The Oldest Electrical Journal, 1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny.
Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	YEAR.	HALF-YEAR.	QUARTER.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* **4** *p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation.*

SPECIAL NOTICE.

Owing to the growth of the electrical and allied industries the demands for space in "THE ELECTRICIAN" are, for the greater part of the year, so pressing that a permanent increase in the size of the journal has become necessary. To meet the increased cost involved by this step, and by other improvements, such as heavier paper and more numerous illustrations, the price of "THE ELECTRICIAN" has from May 3rd been advanced to 6d.

The Subscription to "THE ELECTRICIAN," commencing with Vol. XXXV. (May 3, 1895), is as follows:—

	YEAR.	HALF-YEAR.	QUARTER.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

NOW READY.—Vol. XXXIV. of "THE ELECTRICIAN," bound in strong cloth. Price 12s. 6d., post free 13s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

SINGLE-ACTING HIGH-SPEED ENGINES FOR CENTRAL STATION WORK.

The Paper which Mr. MARK ROBINSON has just read before the Institution of Electrical Engineers came as a direct challenge from a member of the well-known Thames Ditton firm; it was a piece of able but modest pleading as to the excellence of the single-acting high-speed engine in general and of the Willans type in particular. When it is remembered, assuming that Mr. ROBINSON'S figures are correct, that out of 101,390 I.H.P. now installed in electric lighting stations in Great Britain, over one-half, or 53,340 I.H.P., has been supplied by his firm, we offer no apology for referring fully to the many points he so definitely raises. As the author pointed out, the question, though in reality a very wide one, was, in his Paper, narrowed down within very precise limits: are the reasons for the almost unprecedented success of this engine —the central valve engine—to be sought in the late Mr. WILLANS' principle, or are they due to other causes? In the mind of the author there is no doubt; but it may be worth while to examine a little more closely some of his main conclusions.

In this connection it is a matter of extreme regret that the discussion was confined almost entirely to the makers of high-speed engines; the mill-engine makers and advocates were conspicuous by their absence, and it certainly seems as though they had abandoned their claims to share in this work, and were ready to admit in Mr. RAWORTH'S words that

Digitized by Google

they had entirely misunderstood the problem of dynamo driving. There can be no doubt that the question of speed is a most vital one, and a very simple one: Is high-speed in itself a desirable thing or not? And on this we must take side with the author; if the principle is abandoned we are face to face with two difficulties. Either belt or other gearing must be adopted, with all its serious practical disadvantages, its resultant additional complexities and chances of breakdown, not to mention the absolute certainty of a reduction in the efficiency of the plant as an energy transformer, or else the dynamo itself must be radically altered in design, and in a a way which commends itself to few English electrical engineers.

This question of speed being conceded, it remains to consider whether, as the author claims, there is anything in the single-acting engine which makes it certain that it will beat its double-acting rival within the limits of speed and power suitable for electric lighting stations, for that is all its advocate claims for it. Mr. Robinson lays great stress on the fact, and rightly for many reasons, that it is a constant thrust engine; hence, there being no lost motion, wear at the brasses must be small. He, however, in defence of his conclusions, makes certain statements with which we are unable to agree. No doubt the actual rubbing of a brass upon the journal when the lubrication is perfect is a matter of comparatively small moment, but is the lubrication likely to be very perfect with the pressure always upon one side of the brass? Certainly, common experience and the results obtained by the Committee of the Institution of Mechanical Engineers on journal friction do not seem to agree with the view that it can be. It will be remembered that in certain cases they found it almost impossible to introduce the oil between the bearing and the brass, and it seems very possible that the rather high frictional load of the Willans engine, when running light, as compared with the Belliss engine, may be due to the fact that these surfaces are not well lubricated. On the other hand, the beautiful system of lubrication adopted by Messrs. Belliss may suffice to introduce the oil satisfactorily at low loads, and yet perhaps fail to do so at higher ones, thus accounting for the apparent anomaly in Mr. A. Siemens' experiments.

There are two other points on which great stress was laid by the author, and rightly, to which we wish to briefly refer. One was that with the central valve system adopted in the Willans engine the drainage was perfect, and probably none of the ordinary horizontal or vertical engines could compare in this respect with the Willans type. Undoubtedly this is a most important factor in the possible economy of any engine; the late Mr. Willans' experiments, described during a discussion at the Institution of Civil Engineers, on the enormous effect produced by a small coil of pipe (through which live steam could be passed) at the bottom of a cylinder in preventing accumulation of water, were a striking proof of the serious harm comparatively small quantities of water will produce in a steam cylinder, and how it tends to accumulate during the working. The other point is the adoption of the Cornish cycle, or the transfer system in working compound. One at least of the speakers in the subsequent discussion asserted that this transfer stroke had less effect than was claimed, dwelling in his remarks almost entirely on the action of the liner. But this ignores the main difficulty in connection with initial condensation in engines; experimental results have proved conclusively that it is by the clearance surfaces the most serious harm is produced. A jacketed engine with large clearance surfaces unjacketed as is so often the case has, as a matter of fact, but little reduction of initial condensation when compared with a non-jacketed engine. The transfer system most ingeniously saves the clearance surfaces from the range of temperature that the liner walls undergo (though a portion of these even do not have the extreme range); hence it is clear, that the condensation on them, for the same piston velocity, and the same surface per pound of steam, will be greatly diminished. In our opinion this transfer stroke, combined with the practical abolition of all ports, is the secret of the undoubted success of this particular high-speed engine in the matter of steam economy, and for the small practical value of jacketing when applied to them.

It has been frequently urged by the advocates of the slow-speed engine that the high-speed engine is usually a very uneconomical engine in the matter of steam, and as it wears always very badly, no real criterion of the steam consumption in practice can be obtained from the works tests. In this connection, the figures given by Mr. G. M. Clark at the meeting of the Institution of Mechanical Engineers in April last, and quoted by the author of the Paper, are most striking. Careful measurements of the actual steam consumption of one of the Willans engines at a station of the Westminster Electric Supply Corporation, under very different load conditions, brought out the interesting result that the calculated feed deduced from the full-power and light load trials at the works corresponded exactly to the measured feed when the latter was corrected for steam-pipe condensation, &c. This result is a striking confirmation of the accuracy of the so-called Willans law, when applied to these engines, and it shows most conclusively that in this engine electrical engineers possess a motor, the duty of which under most variable conditions is rigorously known; in fact, it is calibrated as accurately for all practical purposes as any of the instruments he is daily using.

The point of importance to users of power in regard to the economy of the high-speed engine is, that though they cannot hope to rival the best performances of slow-speed engines at full power, yet under light and variable loads they do. In fact, the mere knowledge of the steam used by any particular engine at its full power is of little value to the user, unless he also knows well the law of change of consumption with variation of power developed. This is a point too often neglected by advocates of some particular system. The question of durability is, after all, very largely one of good work; if an engine has nothing but the highest class of work put into it, if reasonable care has been exercised in its design, and if it is properly looked after while at work, then probably there is not much to choose between different types of high-speed engines. The facts given by Mr. Robinson, and the testimony of others are clear enough proof, if any were needed, that these engines are not machines which will knock themselves to pieces. Mr. Geipel's statement, that we have no proof that they will last because they have been only such a short time in use, is beside the mark, although they are probably unlikely to last as long as the more costly slow speed rival. Into the question the of value these engines have over the slow-speed engine in allowing a number of convenient-sized units to be arranged for in every station we do not now enter. It is now an article of faith that if economy is to be obtained, our units must be worked at full power as much as possible, and that means extensive subdivision. We can only hope that the welcome which has been accorded to Mr. Robinson's Paper will induce the makers of other types of central station engines to come forward and state their views in an equally lucid and cogent manner, and if they do so, we venture to express the further hope that the user of engines, the central station engineer, will take a more prominent part in the discussion than was the case last week, when the voice of the maker of engines was almost the only one heard in the land.

A CONTRIBUTION TO THE THEORY OF DEMAGNETISATION.

BY EDWIN J. HOUSTON AND A. E. KENNELLY.

It has long been known that in order to retain the magnetism in a permanent magnet of hard steel, certain relations must be maintained between the length and cross-section of the bar as compared with the dimensions of the air-gap between its poles. In other words, it has been known that a certain proportion of the reluctance of the magnetic circuit must exist in the air-gap for a given value in the retentivity or hysteretic coefficient in the steel employed, in order that the magnetism in the circuit should be permanent. Mr. Hookham states in the *Philosophical Magazine* for 1889, Vol. XXVII., pp. 187-189, that from his

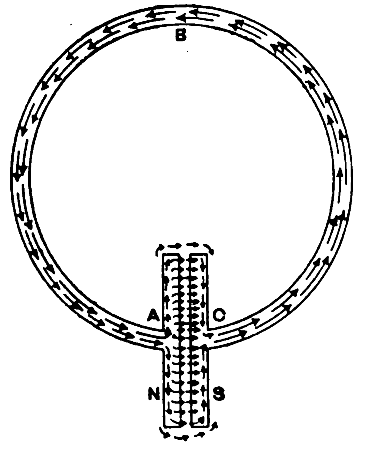

FIG. 1.

observations the ratio of length to cross-section in a magnet should not be less than 70 times the ratio of length to cross-section in its air-gap, in order to retain its magnetism indefinitely. So far as the authors are aware, the numerical theory of demagnetisations in permanent magnets has not been developed except in a few geometrical forms of magnets such as ellipsoids, which rarely present themselves in practice. It is here proposed to present this theory in a general form, and to show the relation existing between this theory and Mr. Hookham's empirical rule.

In Fig. 1, A B C represents a horse-shoe magnet of hard steel, $l$cm. in length, and of uniform cross-sectional area s sq. cms. Fig. 2 represents a portion of the descending

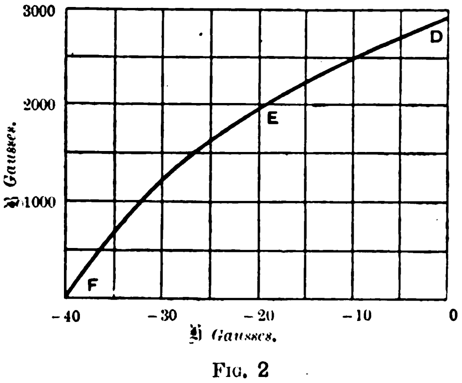

FIG. 2

curve in the hysteretic cycle of this steel. When the ring is magnetised by the application of an M.M.F. to an intensity of, say, 6,000 gausses,* and the M.M.F. is withdrawn, a certain residual intensity of $\mathfrak{B}$ gausses will exist in the bar, and the total residual flux will be $\Phi = \mathfrak{B}\, s$ webers. Of this residual flux a certain fraction Φ/n, or say ϕ, will pass through the air-gap, whose width is d cms., and active cross-section S sq. cms., producing in the air-gap an intensity of Φ/S gausses. The remainder of the flux, or $\Phi - \phi$ webers, will pass through leakage or air-paths outside the air-gap.

Just as in the electric circuit a current of i amperes passing through a resistance of r ohms produces a difference of potential of $e = ir$ volts, so a flux of ϕ webers passing through a reluctance $\mathfrak{R} = d/S$ oersteds in the air-gap will produce a difference of magnetic potential of $\mathfrak{M} = \Phi\mathfrak{R}\ \dfrac{\phi d}{d}$ gilberts. The mean difference of potential per centimetre length of the ring A B C will be $\mathfrak{H} = \dfrac{\mathfrak{M}}{l} = \dfrac{\phi d}{S\,l}$ gausses, and this will be the mean demagnetising force exerted through the bar. The effect of this magnetising force will be to reduce the flux through the bar until the residual intensity $\mathfrak{B} = \dfrac{n\phi}{s}$ is the intensity which corresponds in the descending branch of the hysteretic cycle to the demagnetising force $\mathfrak{H} = \dfrac{\phi d}{S\,l}$. As soon as the residual flux descends to this intensity, equilibrium will be reached. The equilibrium is, however, unstable, for any mechanical agitation or variation of temperature to which the bar may be subjected in the presence of this demagnetising force will cause a further demagnetisation to take place. In order, therefore, that a magnet should not be liable to variations in its intensity owing to slight accidental jars or variations of temperature, it is necessary that the demagnetising force $\mathfrak{H} = \dfrac{\phi d}{S\,l}$ should be considerably less than the value of $\mathfrak{H}$ which corresponds to the residual intensity $\mathfrak{B} = \dfrac{n\phi}{s}$ in the descending curve of the cyclic diagram for the quality of steel employed. The ratio of the cyclic value to the actual value of $\mathfrak{H}$ may be called the *factor of safety of demagnetisation.* According to the experiments of the authors, a reliable factor of safety is 3, and this factor of safety can usually be provided by proportioning the length and cross-section of the magnet and of the air-gap with reference to the hysteretic curve of the steel employed.

Suppose, for example, that an air-gap has to be provided 0·5cm. in width, and 10 sq. cms. in active cross-sectional area. Let the desired residual intensity in the steel be 1,500 gausses, and in the gap 600; also let the assumed value of the leakage factor $n = 1{\cdot}3$, and D E F (Fig. 2) be the descending curve of magnetisation for the steel employed. Then the flux $\phi = 1{,}500\ s = 600 \times 10 \times 1{\cdot}3$, or $s = 5{\cdot}2$, so that the cross-section of the magnet must be 5·2 sq. cms. The cyclic value of $\mathfrak{H}$ which corresponds to $\mathfrak{B} = 1{,}500$ is 26, so that with a factor of safety of 3 the value required is 8·7. The M.M.F. in the air-gap will be $600 \times 0{\cdot}5 = 300$ gausses, and the mean $\mathfrak{H} = \dfrac{300}{l} = 8{\cdot}7$, so that $l = 34{\cdot}4$. The length of the ring must, therefore, be 34·4cms.

With such a length provided, and with an intensity set up in the bar of, say, 6,000 gausses under the magnetising M.M.F., a powerful counter M.M.F. would tend to be set up on its withdrawal. If, for example, 6,000 gausses remained in the bar, the intensity in the gap would be 2,400, and the demagnetising force 34·8. Reference, however, to Fig. 2 shows that such a demagnetising force would reduce the residual intensity to about $\mathfrak{B} = 750$, at which the demagnetising force would only average 4·35 gausses. It is evident, therefore, that the intensity would fall along the line D.E.F. until equilibrium is reached between the intensity and demagnetising force. This would be met under the assumed conditions at $\mathfrak{B} = 2{,}250$ approximately. That is to say, if the magnet were allowed to assume its natural condition, the intensity in the steel would fall to about 2,250 gausses, and the demagnetising force rise to about 13 gausses, and this condition would be unstable, being probably followed by a slow and gradual decline in intensity under mechanical or thermal agitation. The process of seasoning a magnet consists, therefore, in designedly lowering its intensity below the natural intensity of equilibrium, so that the residual demagnetising force may then be too small to precipitate further demagnetisation, even when aided by considerable mechanical or thermal disturbance. Thus, if the magnet be

* [For the benefit of the uninitiated, we may remark that the names "gilbert," "weber," "oersted" and "gauss" were provisionally adopted by the American Institute of Electrical Engineers at its meeting of March 21, 1894, for the C.G.S. units of magnetomotive force, magnetic flux, reluctance, and flux-density.—ED. *E.*]

Digitized by Google

boiled in water or oil, or its air-gap be momentarily widened, or if it be violently agitated, the intensity may be reduced to 1,500 gausses with a corresponding demagnetising force of 8·7, which is three times less than the cyclic force required to reduce the intensity still further.

If the magnet is not properly designed it will, after seasoning, be either unnecessarily heavy for the work it has to perform, or unduly weak in residual intensity.

Since $$\mathfrak{B} = \frac{n\phi}{s} \text{ and } \mathfrak{H} = \frac{\phi d}{S l}$$

$$\frac{1}{n} \cdot \frac{\mathfrak{B}}{\mathfrak{H}} = \frac{l}{s} \Big/ \frac{d}{S}.$$

So that if $\mathfrak{B}$, the remanent intensity, be given an assigned value, $\mathfrak{H}$, defined as being, say, one third of the cyclic value corresponding thereto, bears a fixed ratio to $\mathfrak{B}$, and $\frac{1}{n} \cdot \frac{\mathfrak{B}}{\mathfrak{H}}$ is for magnets of the same form and material a definite numerical quantity, which is the ratio of l/s in the steel to d/s in the air-gap.

According to Mr. Hookham's formula, this ratio is not less than 70. Assuming that the intensity in the steel he employed was 2,000, that it was powerfully magnetised at the outset, and that n was 1·3 in his magnetic circuit, then $\frac{1{,}000}{1{\cdot}3\,\mathfrak{H}} = 70$ or $\mathfrak{H} = 11$ approximately, while the cyclic value of $\mathfrak{H}$, corresponding to $\mathfrak{B} = 1{,}000$ is 33 gausses, giving a safety factor of 3.

In the well-known Weston permanent magnet ammeters and voltmeters, the accuracy of the instruments depends upon the permanence of the conditions existing in the magnetic circuits. The length of a particular Weston horse-shoe magnet is 27cms., its cross-sectional area 2·7 sq.cms. There are two air-gaps in series, each approximately 0·275cm. long and 11 sq. cms. in cross-section, offering, therefore, a total reluctance of approximately 0·05 oersted. The intensity in the steel is approximately 1,250 gausses, and the total useful flux through the air-gap 2,500 webers, making the total C.M.M.F. 2,500 × 0·05 = 125 gilberts, and the mean demagnetising force $\frac{125}{27}$, or nearly 5 gausses. For steel with a cyclic curve, as represented in Fig. 2, this would represent a factor of safety of 6, and the well-known satisfactory permanence in the magnetism of these instruments is no doubt owing to a large magnetic safety factor.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(Continued from page 126.)

40. Kennelly's Break Test.—It has long been observed in measuring through a break or fault making fairly good earth that the total resistance decreases as the testing current is increased, and the existence of some law governing the change of resistance was suspected and hinted at by several observers. The importance of knowing this law was evident to all who had to deal with the repair of cables, and some reference was made to the subject by Sir Henry Mance in the Paper above alluded to. It was left to Mr. A. E. Kennelly, who has developed the higher order of cable testing, to discover the law and its practical limitations, as the result of a long series of observations with different currents and areas of exposure. This law, which is known as "the law of inverse square roots," is briefly stated as follows:—The resistance of an exposed conductor varies inversely as the square root of the current sent through it. The subject was first made public in a Paper by Mr. Kennelly before the then Society of Telegraph Engineers and Electricians in March, 1887, on "The Resistance of Faults in Submarine Cables." The practical conditions and limitations may be stated as follows:—

(1) *Area of Exposure.*—The law is based upon gas development at the break, and has apparently its origin in this gas and its rate of discharge from the exposure. If the area of bare copper conductor exposed at the break is very small or is partially covered by the broken ends of the percha, the gas will not escape freely, but will cling to and accumulate on the obstructions, and when this is so the law does not hold good. Roughly, if the net area allowing free gaseous discharge is less than about half a square centimetre, the accumulation of gas forms a mechanical insulation which causes a less rapid fall in the resistance with a given increase of current, the variation being then more nearly as the inverse cube or fourth root of the current.

(2) *Strength of Battery Current.*—On account of the difficulty in measuring the true earth and polarisation currents active in the cable during the test, an error is introduced which makes the result somewhat too high. The deflection caused by these currents is read on the galvanometer as soon after breaking the testing current as possible, and the position on the scale treated as the false zero; but some seconds elapse before it can be observed, in consequence of the electrostatic discharge from the cable. And, as the E.M.F. of polarisation rapidly falls, the correct value to assign for false zero is not definitely determinable. The error, however, is almost inappreciable if the strength of current used in the test does not exceed 25 milliamperes.

On this point Mr. Kennelly says:—"A certain zero is assumed to start with as the false zero to work to; namely, the polarisation or cable current then existing. The battery key is then depressed and balance adjusted till this zero is maintained. The key is then released. Let O X represent

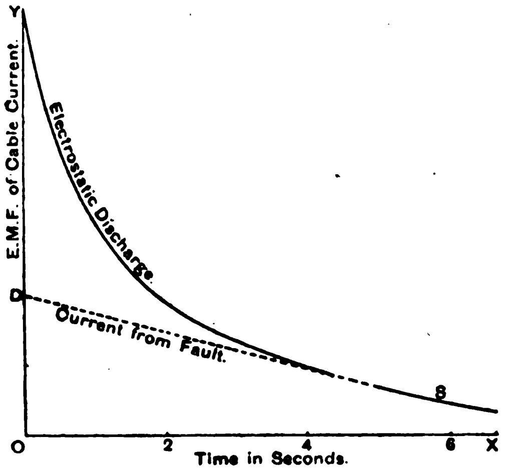

FIG. 110.

time, and O Y the observed discharge on the galvanometer (Fig. 110). Now, assuming the truth of the law, it can only be strictly applicable when the false zero is immediate—namely, when it is the first throw observed on releasing the battery key indicating less resistance. If there is no appreciable electrostatic or electromagnetic capacity in the cable or bridge to disturb the galvanometer on opening or closing the battery circuit, the rush of the spot in the first direction must be due to the polarisation electromotive force existing in the exposure circuit during the last moments of testing current flow, and consequently the correct position of the spot to select as zero is that position which in its first throw it endeavours to reach. Accordingly, in the experiments which established the law, the balancing resistance was reduced step by step until this first throw was so far diminished as to be no longer appreciable.

"If there were no electrostatic or electromagnetic capacity in the cable and bridge, the curve D S would represent the discharge due to depolarisation. It would then be possible to read to the first throw O D of the needle, or to 'immediate false zero;' but the electrostatic capacity discharge is superposed, and creates the discharge curve Y S. After a certain interval the electrostatic discharge is over, and the curves coincide. It is of no use to take any position of the spot as the false zero until that has taken place. All that can be done is to estimate by experience the point at which the electrostatic effect has disappeared, and to take that point as the false zero. It is

Digitized by Google

neither theoretically nor practically correct, but the error for small currents (not exceeding 25 milliamperes) is generally small, except when the length of cable in circuit is under 50 or over 5,000 ohms. It is the best approximation that can be made.

"The balance is therefore made while the battery current is on, to that point taken as zero, determined as soon as possible after the battery is taken off. The period of time elapsing before fixing upon the false zero is much greater with a long than with a short cable. Fortunately the error produced is not great within the limits named."

(3) *Steadiness of Battery Current.*—The E.M.F. of the testing battery must be constant during the test. If it falls at all, the current through the break is reduced in proportion and affects the result. It is generally well to use plenty of battery power with resistance added to keep the current within the limit of 25 milliamperes, such as, say, 50 good Leclanché cells.

The periods of applying the battery for testing need not be long, and as the output does not exceed one quarter of an ampere, the E.M.F. should keep sufficiently constant. Any preliminary hard work in breaking down the resistance of the fault or cleaning it by a zinc current sustained for periods exceeding ten minutes should be done by a battery of Minotto cells.

(4) *Direction of Battery Current.*—Preliminary bridge tests taken when first communication is interrupted will show whether the fracture polarises with the zinc or copper current. Generally, of course, it polarises with the copper and breaks down with the zinc, signifying an exposure of copper at the break. It happens sometimes, however, that the bare conductor at the fracture is buried in mud, thus preventing the gas evolved by the zinc current from escaping and stopping any deposition of salts with the copper current. Under these circumstances the break is very variable, and sometimes polarises with a zinc and not with a copper current. The direction of current used in testing is always that which breaks down the resistance of a fault or fracture, or keeps it low and does not allow it to rise. This direction is almost always zinc to line; but if the break polarises with zinc as described (which, however, is a rare occurrence) the test can be taken with copper current, which, under these circumstances, gives the lowest results and follows the law with currents up to 25 milliamperes.

(5) *Distance of Break.*—Even with large exposures if they are a long way off the necessary range of current cannot be sent through them, partly because the testing E.M.F. is limited by the rules and partly on account of the intervening resistance of the cable. The battery power is generally limited to 50 volts. Under these circumstances, allowing, say, 200 ohms for battery and bridge, it will be seen that 25 milliamperes cannot be sent through the break if it is more than 1,800 ohms away. If it is further off, fairly reliable tests can be obtained with currents that can then be forced through, say up to 12 or 16 milliamperes; but if the break is 5,000 or more ohms distant the test cannot be applied owing to insufficient current reaching the break. It is not often, however, that breaks are more than 100 miles from shore.

In taking the test various strengths of currents must be used, but not exceeding 25 milliamperes. If A is the bridge reading with a current to line of c milliamperes and B that with c_1 milliamperes, x being required distance to break in ohms, we have—

$$\text{Resistance of break with current } c = A - x,$$
$$\text{,, \quad ,, \quad ,, \quad ,, } \quad c_1 = B - x.$$

And, by the law of inverse square roots, these resistances are inversely proportional to the square root of the currents; that is

$$\frac{A - x}{B - x} = \frac{\sqrt{c_1}}{\sqrt{c}},$$

whence
$$x = \frac{A\sqrt{c} - B\sqrt{c_1}}{\sqrt{c} - \sqrt{c_1}} \text{ ohms.}$$

It is convenient to use currents only in the proportion of 1 to 4. Then $c_1 = 4c$ and $\sqrt{c_1} = 2\sqrt{c}$, and the distance of break becomes

$$2\,B - A \text{ ohms,}$$

or in its more convenient form

$$B - (A - B) \text{ ohms.}$$

The explanation of this is that, by the law of inverse squares, the resistance of the break is halved when the current is four times the strength. The reading A gives distance to break, plus resistance of break, while the reading B gives distance to break, plus half the former resistance of break. The difference between the readings A and B is therefore equal to the resistance of the break when the B reading was taken. Therefore, subtracting the difference of any pair of readings (currents used for which are as one to four) from the lowest one of the pair gives the distance of break in ohms.

The following 12 currents give 6 pairs in the ratio of 1 to 4, viz.:—

1	2	3	4	5	6
4	8	12	16	20	24

If low resistance cells are used, of about one or two ohms per cell, the currents to line are sufficiently nearly proportional to the number of cells in series in the testing battery, and with equal ratios in the bridge arms the current to line in milliamperes is found by

$$\frac{E}{2\,b + a + A},$$

where E = volts of testing battery,
b = resistance of testing battery,
a = one bridge arm,
A = balancing resistance

with each variation of battery. Suppose a reading of 1,040 ohms is obtained (to false zero) with a battery of 7 volts and 5 ohms, and again another reading of 1,020 with battery of 28 volts and 20 ohms, ratio of bridge 1,000/1,000.

Neglecting earth current, the currents used were respectively,

$$\frac{7}{10 + 1{,}000 + 1{,}040} = 3{\cdot}4 \text{ milliamperes,}$$

and
$$\frac{28}{40 + 1{,}000 + 1{,}020} = 13{\cdot}6 \text{ milliamperes,}$$

or in the ratio of 1 to 4. Therefore, the distance of break is

$$1{,}020 - 20 = 1{,}000 \text{ ohms.}$$

The currents to line may also be varied and calculated by varying the amount of resistance in the battery circuit, the number of cells in the testing battery being constant.

With the bridge arms unequal, say a ohms on the cable side, and μa ohms on the coils side, as in Fig. 111, the equation for the current through the cable is—

$$\frac{E}{(\rho + b)\left(\frac{\mu + 1}{\mu}\right) + a + R} = \frac{n}{1{,}000},$$

where E = E.M.F. of battery,
b = resistance of battery,
ρ = added resistance to battery,
a = arm of bridge on cable side,
μa = arm of bridge on coils side,
R = resistance unplugged to balance,
n = number of milliamperes required,

From which we obtain an equation for the added resistance for any current of n milliamperes

$$\rho = \left(\frac{1{,}000\,E}{n} \times \frac{\mu}{\mu + 1}\right) - \frac{a\mu}{1 + \mu} - b - R\,\frac{\mu}{\mu + 1}.$$

With a bridge ratio of 1,000/1,000, μ is unity, and

$$\rho = \left(\frac{1{,}000\,E}{n} \times \frac{1}{2}\right) - \frac{1{,}000}{2} - b - \frac{R}{2}.$$

$$= 500\left(\frac{E}{n} - 1\right) - b - \frac{R}{2}$$

The first two terms can be calculated permanently for this bridge ratio, the third (the battery resistance) can be measured

Digitized by Google

just before the test and deducted. A preliminary test with this resistance (calculated from the above three terms) added to battery is taken to get a value for R. Then the added resistance is reduced by half of R, and the test repeated, giving the required result A.

To obtain the result B, the value of n is made four times its former amount. The resistance to add is then worked out as before, and the balance obtained with this resistance in circuit.

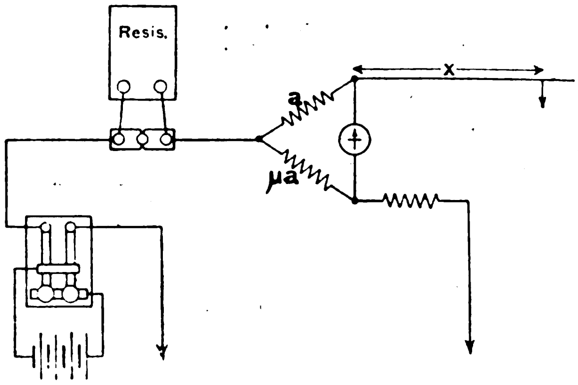

FIG. 111.—Kennelly's Test for Break.

It is convenient to work out tables for the different currents named and for different bridge ratios of the first two terms of the equation for added resistance. Thus, with a battery of 60 volts and 40 ohms, we can calculate the resistances as follows:—

Current to line in milliamperes.	For bridge ratios of		
	1000/1000	100/100	100/1000
1	29,460	29,910	54,414
2	14,460	14,910	27,142
Inter	mediate	values	
20	960	1,410	2,596
24	710	1,160	2,142

With the ratio 100/1000 $\mu = 10$, and the formula for added resistance becomes

$$\rho = \frac{10{,}000\,E}{11n} - \frac{1{,}000}{11} - b - \frac{10R}{11}\ \text{ohms.}$$

The resistances so calculated are further reduced during the progress of the tests, in the case of equal ratios by half the resistance unplugged to balance, and in the case of 100/1000 by $\frac{10}{11}$ of the resistance unplugged to balance; after which the balances obtained give the results required with the given currents.

These tests are all taken to false zero, and depend upon the earth current keeping fairly constant during a pair of readings. The effect of variation in the earth current is, however, reduced to a minimum by using a high E.M.F. in the testing battery. If there is no dead-beat galvanometer available, such as already described, the marine galvanometer must be used; but it is no easy matter to read to false zero with this galvanometer.

For these reasons the test with three readings to instrument zero, described in the last paragraph, is preferable, although somewhat more lengthy, because variations in the earth current are accounted for, and it is a null method, requiring no special galvanometer.

The instrument zero method has the further advantage of not being limited to 25 milliamperes, since it measures the true value of the polarisation current, which the false zero method can never do, in consequence of the interference of the electrostatic discharge. On the other hand, any errors due to deviation of the resistance of the break from the law of inverse squares, or to the variation of polarisation current, are less in the false zero than in the instrument zero method.

If a second galvanometer is available it may be used in the cable circuit to indicate the current passing into the cable. It must be shunted with a piece of wire, the size and length of which is adjusted to produce a convenient deflection when maximum current is passing. This saves calculation of resistances, the latter being simply adjusted until the deflection required is produced. The scale of such a galvanometer could be calibrated direct in milliamperes. A reflecting galvanometer for this purpose is rather too great a refinement on board ship, and few ships' testing tables are big enough for two galvanometers working at once. The author has suggested the use of a portable milliamperemeter for this purpose, and has devised a form whose indications are dead-beat and not affected mechanically or magnetically by the rolling of the ship. This instrument can be placed directly in the cable circuit, and reads directly in milliamperes; its use saves the time taken in calculations and trial tests to obtain the correct resistance for a definite current to line.

(To be continued.)

IMPROVEMENTS IN ARMATURE VENTILATION.*

BY PROF. HARRIS J. RYAN.

In the type of armature used in America during 1880-1890 the author states that the ventilation for an armature moving at a peripheral velocity of 3,000ft. per minute is 0·034 watts per sq. in. of surface per degree centigrade rise of temperature above that of the surrounding atmosphere. These two-pole armatures were rated at 75°C. rise of temperature, the hysteresis and eddy losses in the core usually causing a rise of 20°C., so that the $C^2 R$ losses in the conductors at full output caused an additional rise of 75 − 20° or 55°C. For a copper conductor 1in. long. and 1in. wide, mounted on this armature core, there will be the following relation between current in amperes and depth or thickness in inches for an increase of temperature of 55°C.

$$C^2 R = 0{\cdot}034 \times 55 = 1{\cdot}87 \text{ watts.}$$

Resistance of 1 mil ft. of copper at 95°C. = 12·5 ohms.

$$R = \frac{12{\cdot}5 \times \frac{1}{12}}{10^6 \times \frac{4}{\pi} \times D},$$

where D is the depth in inches.

$$C^2 R = C^2 \frac{12{\cdot}5 \times \frac{1}{12}}{10^6 \times \frac{4}{\pi} \times D} = 1{\cdot}87$$

$$C^2 = \frac{1{\cdot}87 \times \frac{4}{\pi} \times 10^6}{12{\cdot}5 \times \frac{1}{12}} D$$

(1) $C^2 = 2{\cdot}3 \times 10^6\,D$ and

(2) $R = 0{\cdot}83 \times 10^{-6} \frac{1}{D}$ is the relation between the resistance in ohms and the thickness in inches for such a copper conductor 1in. long and 1in. wide. Equation (1) teaches us that for a fixed allowable rise of temperature the square of the current output will vary as the depth of the copper.

Where T is the rise of temperature in degrees centigrade produced by $C^2 R$ heating in these armatures, we have this relation:—

$$T = \frac{R}{0{\cdot}034} C^2$$

differentiating, $$\frac{dT}{dC} = \frac{RC}{0{\cdot}017}. \qquad (3)$$

Equation (3) enables us to determine the rate at which T is increasing with respect to C.

The author concludes that there is a great need of improved facilities for armature ventilation. Since 1890 there has been a steady improvement in this respect. The demand for slow-speed electrical machinery has caused the development of the multipolar types with short hollow armatures of large diameters that are naturally much better venitlated than the two-pole types. In addition to this, ventilating flues in the laminated cores of "iron-clad" armatures are provided without weakening the structure. Through these modifications the ventilation has been increased very materially, the effect of which is to increase the radiation coefficient from 0·034 to 0·04 and probably 0·06 in some instances. The result is that makers have been able to deliver machines rated at a lower temperature increase, which will stand from 10 per cent. to 20 per cent. continued overload.

At present along orthodox lines of practice there is little incentive to modify designs so as to gain still further ventilation, owing to the fact that with the present methods machines may be loaded to the sparking limit without overheating. The sparking limit

* Abstract from the April number of the *Sibley Journal of Engineering.*

Digitized by Google

may, however, be entirely removed by the use of a commutation lug and pole-face coils for balancing the armature reaction (see *The Electrician*, Vol. XXXIV., April 19th, p. 765) and regulating the induction at the commutation lug so as to be proportional to the output. To take full advantage of this improvement it is necessary to improve the armature ventilation to the greatest available extent without sacrifice. To do this Mr. M. E. Thompson adopts a short multipolar armature of large diameter, with windings whose cross connections are in the same cylindrical outline as the armature itself, and so disposed that they form a system of numerous flues through which great quantities of air are passed from moment to moment. Little dependence is placed on the ventilation from the smooth surfaces of the armature. The conductors are so short that a small difference of temperature suffices to carry the developed heat from the centre of the armature to the cross connections, where it is rapidly taken up by the radial air currents. Armatures recently built on this system and thoroughly tested show that ventilation is provided which is proportional to the depth of armature copper. Thus the maker is at liberty to select precisely those proportions of iron and copper and working induction and current densities that will give desired performances as to efficiency and durability at the lowest first cost.

DRAFT REGULATIONS AND CONDITIONS FOR SECURING THE SAFETY OF THE PUBLIC.

The following set of rules and regulations has recently been issued by the Board of Trade to central station engineers and others. Comments are invited. With a view of facilitating the work of comparison, we print below the proposed new rules in full. The portions in italics denote either considerable alteration as compared with previously issued rules or complete novelty:—

DEFINITION.

In the following regulations—

The expression "the Order" means the ——— Order.

The expression "the Undertakers" means the Undertakers for the purpose of the Order.

The expression "consumer's wires" means any electric lines on a consumer's premises which are connected with the service lines of the Undertakers at the consumer's terminals.

The expression "aerial line" means any electric line which is placed above ground and in the open air.

The expression "pressure" means the difference of electrical potential between any two conductors through which a supply of energy is given, or between any part of either conductor and the earth; pressure on any alternating-current system being taken to be the equivalent of pressure on a continuous-current system when it produces an equal heating effect if applied to the ends of a thin stretched wire or carbon filament; and—

(*a*) Where the conditions of the supply are such that the pressure cannot at any time exceed 300 volts, if continuous, or the equivalent of 150 volts, if alternating, the supply shall be deemed a low-pressure supply:

(*b*) Where the conditions of the supply are such that the pressure may exceed the limits of a low-pressure supply, but cannot exceed 3,000 volts, or the equivalent of 3,000 volts, whether continuous or alternating, the supply shall be deemed a high-pressure supply:

(*c*) Where the conditions of the supply are such that the pressure may on either system exceed 3,000 volts or the equivalent of 3,000 volts, the supply shall be deemed an extra high pressure supply.

Mains, service lines, and other conductors and apparatus are referred to as low-pressure, high-pressure, and extra high-pressure mains, &c., according to the conditions of the supply delivered through the same or particular portions thereof.

Where these regulations require any metallic body to be "efficiently connected with earth," it shall be connected with the general mass of earth in such manner as will ensure at all times an immediate and safe discharge of electrical energy.

Other expressions to which meanings are assigned in the Order or principal Act have the same respective meanings in these regulations.

A.—REGULATIONS AS TO SAFETY.

I. GENERAL.

Low-pressure supply to customers. 1. Save as hereinafter provided, the supply of energy delivered to the consumer's terminals shall be a low-pressure supply.

Limitations of high-pressure supply. 2. A high-pressure supply shall not be delivered to any consumer's terminals, except for special purposes, and with the approval of the Board of Trade on the joint application of the consumer and the Undertakers, and subject to such further regulations as the Board of Trade may from time to time prescribe. But a high-pressure supply may be given to distributing or converting stations, *or to transforming apparatus on a consumer's premises*, in accordance with the following regulations.

Limitations of extra high-pressure supply. 3. An extra high-pressure supply shall not be given except to distributing stations or other premises in the sole occupation of the Undertakers, and with the written consent of the Board of Trade, and subject to such regulations and conditions as the Board may prescribe.

Limit of power in high-pressure electric line. 4. *No high-pressure electric line shall be used for the transmission of more than 200,000 watts, or in the case of an aerial line 50,000 watts, except with the consent in writing of the Board of Trade, and efficient means shall be provided to prevent this limit being at any time exceeded.*

Quick-acting cut-off for high-pressure lines, &c. 5. *Every high-pressure electric line, conductor, or other apparatus shall be protected by a suitable automatic quick-acting cut-off.*

Transformers. 6. In every case where any transforming apparatus is used to convert a high-pressure supply into a low-pressure supply, some suitable automatic and quick-acting means shall be provided to protect the low-pressure system from any accidental contact with or leakage from the high-pressure system, either within or without the transforming apparatus.

Maximum current in conductors. 7. The maximum working current in any conductor shall not be sufficient to raise the temperature of the conductor or any part thereof to such an extent as to materially alter the physical condition or specific resistance of the insulating covering, if any, or in any case to raise such temperature to a greater extent than 30°Fahr.; and efficient automatic means shall be provided which will render it impossible for this maximum working current to exceed such limit to the extent of 50 per cent., even for short intervals of time: and special care shall be taken that the cross-sectional area and conductivity at joints are sufficient to avoid local heating, and that the joints are protected against corrosion.

Minimum size of conductors. 8. *The sectional area of the conductor in any electric line laid or erected in any street shall not be less than the area of a circle of one-tenth of an inch diameter, and when the conductor is formed of a strand of wires each separate wire shall be at least as large as No. 20 standard wire gauge.*

Insulation test of electric lines. 9. *Every electric line shall be tested for insulation after having been placed in position, the testing pressure being at least 200 volts, and the Undertakers shall duly record the results of the tests of each line or section of a line. No electric line shall be brought into use in which this test indicates an insulation resistance less than at the rate of 100,000 ohms per mile for every volt of pressure of the supply, unless it is connected with earth with the consent of the Board of Trade, in which case the insulation resistance of such electric line shall not be less than 10 megohms.*

Maintenance of insulation. 10. *The insulation of every complete circuit used for the supply of energy, including all machinery, apparatus, and devices forming part of, or in connection with, such circuit, shall be so maintained that the leakage current shall not under any conditions exceed one-thousandth part of the maximum supply current; and suitable means shall be provided for the immediate indication and localisation of faults of insulation. Every such fault shall be remedied without delay.*

Every such circuit shall be tested for insulation at least once in every week, and the Undertakers shall duly record the results of such testings.

Provided that where the Board of Trade have approved of any part of any electric circuit being connected with earth, the provisions of this regulation shall not apply to such circuit so long as such connection exists.

Specification of insulating material. 11. *All material used for insulating electric lines or apparatus shall be of the best quality, and thoroughly durable and efficient, having regard to the conditions of its use. Suitable provision shall be made for the protection of the insulating material against injury or removal.*

High-pressure conductors to be covered. 12. Every high-pressure conductor shall be continuously covered with insulating material to a thickness of not less than one-tenth part of an inch, and in cases where the extreme difference of potential in the circuit exceeds 2,000 volts, the thickness of insulating material shall not be less in inches or parts of an inch than the number obtained by dividing the number expressing the volts by 20,000. If this protection be wholly or partly metallic, it shall be efficiently connected with earth.

Testing of insulation of all parts of any high-pressure circuit. 13. *No electric line, machine, device, or apparatus intended to form part of, or be connected with, a high-pressure circuit shall be brought into use unless the insulation thereof has withstood the continuous application during one hour of twice the pressure to which it is intended to be subjected in use.*

The Undertakers shall duly record the results of such test.

Protection from lightning. 14. Where any portion of any electric line or any support for an electric line is exposed in such a position as to be liable to injury from lightning, it shall be efficiently protected against such injury.

Accidents to be reported. 15. *Where any accident by fire or explosion, or any accident causing or likely to have caused personal injury, occurs at any part of any electric line or work to which these regulations apply, the Undertakers shall give immediate notice thereof to the Board of Trade.*

II. AERIAL LINES WHERE ERECTED WITH THE NECESSARY CONSENTS.

Maximum intervals between supports. 16. Every aerial line shall be attached to supports at intervals not exceeding 200ft. where the direction of the line is straight, or 150ft. where this direction is curved, or where the line makes a horizontal angle at the point of support.

Digitized by Google

Supports, construction and erection of. 17. Every support of aerial lines shall be of a durable material, and properly stayed against forces due to wind pressure, change of direction of the lines, or unequal lengths of span. The factor of safety for the lines and suspending wires shall be at least 6, and for all other parts of the structure at least 12, taking the maximum possible wind pressure at 50lb. per square foot. No addition need be made for a possible accumulation of snow.

Every support, if of metal, shall be efficiently connected with earth.

Attachment of aerial lines. 18. Aerial lines* shall be attached to insulators, and shall be so guarded that they cannot fall away from the support. *Conductors covered with insulating material shall not be attached to the insulators by metal binders.*

Height from ground and distance from buildings, &c. 19. An aerial line shall not in any part thereof be at a less height from the ground than *18ft.*, or where it crosses a street, *30ft.*,† *or within 5ft. measured horizontally*, or 7ft. measured vertically, from any building or erection other than a support for the line, except where brought into a building for the purpose of supply.

Service lines from aerial lines. 20. Service lines from aerial lines shall be led as directly as possible to insulators firmly attached to some portion of the consumer's premises which is not accessible to any person without the use of a ladder or other special appliance, and from this point of attachment they shall be enclosed and protected in accordance with the regulations hereinafter contained as to service lines on the consumer's premises. *Every portion of any service line which is outside a building but is within 7ft. from such building shall be completely enclosed in stout india-rubber tubing.*

Angle of crossing thoroughfares. 21. Where an aerial line crosses a street, the angle between such line and the direction of the street at the place of such crossing shall not be less than 60deg., and the spans shall be as short as possible.

Crossing wires, &c. 22. *Where an aerial line crosses, or is in proximity to, any metallic substance, precautions shall be taken by the Undertakers against the possibility of their line coming into contact with such metallic substance, or of such metallic substance coming into contact with their line by breakage or otherwise.*

Suspending wires. 23. Every high-pressure aerial line shall be efficiently suspended by means of insulating ligaments to suspending wires, so that the weight of the line does not produce any sensible stress in the direction of its length. All suspending wires, if of iron or steel, shall be galvanised.

Discharge of pressure in case of fire. 24. *In the case of any aerial line exceeding one half-mile in total length, means shall be provided whereby the pressure may be discharged from any portion of such line erected over or alongside of any building or buildings without loss of time in case of fire or other emergency.*

Maintenance. 25. Every aerial line, including its supports and all the structural parts and electrical appliances and devices belonging to or connected with such line, shall be duly and efficiently supervised and maintained as regards both electrical and mechanical conditions.

Unused aerial lines to be removed. 26. An aerial line shall not be permitted to remain erected after it has ceased to be used for the supply of energy, unless the Undertakers intend within a reasonable time again to take it into use.

III.—Electric Lines other than Aerial Lines.

Conduits to be durable and strong. 27. All conduits, pipes, or casings used as receptacles for electric lines shall be constructed of durable material, and of ample strength to prevent damage from heavy traffic, and where they are laid in streets in which gas mains are also laid shall be so constructed as to prevent any influx of gas from the adjacent soil.

Crossing pipes, &c. 28. *Where any electric line crosses, or is in proximity to, any metallic substance, special precautions shall be taken by the Undertakers against the possibility of any electrical discharge to the metallic substance from their line or from any metal conduit pipe or casing enclosing their line.*

Electric continuity of metal conduits, pipes, or casing. 29. *All metal conduits, pipes, or casings containing any electric line shall be efficiently connected with earth; and shall be so jointed and connected across all street boxes and other openings as to make good electrical connection throughout their whole length.*

Precautions against charging of short lengths of pipe, &c. 30. *Where isolated lengths of metal conduit, pipe, or casing are used for the protection of any electric line at road crossings or similar positions, there shall be interposed between such electric line and the conduit, pipe, or casing such additional insulating material as will prevent the possibility of any electrical charging thereof.*

Precautions to be taken when bare conductors are used. 31. *Where the conductors of electric lines placed in any conduit are not continuously covered with insulating material, they shall be securely fixed in position, and no unfixed material of a conducting nature shall be contained in the conduit.*

Adequate precautions shall also be taken to ensure that no accumulation of water shall take place in any part of the conduit, and to prevent any access of moisture to the conductors or the insulators, and the latter shall be so disposed that they can be readily inspected.

* No mention of the "bearer" wires as in the old rules.—Ed. *E.*

† Note.—In the County of London, 35ft.

High-pressure lines laid above ground. 32. Any portions of any high-pressure electric lines placed above the surface of the ground, or in any subway, shall be completely enclosed either *in a highly-glazed porcelain tube* embedded in brickwork, masonry, or cement concrete, or in strong metal casing efficiently connected with earth, *and so protected and guarded as to prevent accidental contact with the casing.*

Treatment of high-pressure lines transmitting considerable power. 33. *Every high-pressure electric line transmitting more than 50,000 watts, or used for the supply of energy to transformers placed in street boxes, shall, except within the generating station, be entirely enclosed in strong metal casing efficiently connected with earth, and such casing shall not contain any low-pressure electric line.*

Ditto where the power transmitted is not more than 50,000 watts. 34. *High-pressure electric lines not intended to transmit more than 50,000 watts may be enclosed either as provided in the preceding regulation, or in glazed stoneware casings properly laid and jointed in cement at a depth of not less than 2ft. below the surface of the ground and sufficiently protected against breakage.*

IV.—Street Boxes.

Precautions with respect to street boxes. 35. *All street boxes which contain any vacant space shall be so constructed as to prevent any influx of gas or water either from the adjacent soil or by means of any pipes and ample provision shall be made by ventilation or otherwise for the immediate escape of any gas which may by accident have obtained access to the box and for the prevention of danger from sparking.*

Covers of street boxes. 36. *The covers of street boxes shall be properly secured, and shall, where the box contains high-pressure apparatus, be connected to strips of metal laid immediately underneath the adjacent roadway or pavement.*

Casing of high-pressure lines in street boxes. 37. *The casing of any high-pressure electric lines shall be continued within street boxes.*

V.—Converting Stations.

Converting stations. 38. All converting stations, or points in a system of distribution to which a high-pressure supply is given from generating stations, and from which a low-pressure supply is given to consumers, shall be established in suitable places, which are in the sole occupation and charge of the Undertakers.

VI.—Consumer's Premises.

Responsibility of Undertakers for their lines, &c., on consumer's premises. 39. The undertakers shall be responsible for all electric lines, fittings, and apparatus belonging to them, or under their control, which may be upon the consumer's premises being maintained in a safe condition and in all respects for supplying energy.

Fire risks. 40. In delivering the energy to the consumer's terminal the undertakers shall exercise all due precautions so as to avoid risk of causing fire on the premises.

Main fuses or disconnectors to be provided in a locked receptacle. 41. *A suitable safety fuse or other automatic disconnector shall be inserted in each service line as close as possible to the point of entry to any consumer's premises, and contained within a suitable locked receptacle of fireproof construction.*

Treatment of low-pressure lines and apparatus. 42. *All low-pressure electric lines and apparatus placed on any consumer's premises shall be highly insulated and thoroughly protected against injury to the insulation or access of moisture, and no metal forming part of the electric circuit shall be exposed so that it can be touched. All electric lines shall be so fixed and protected as to prevent the possibility of electrical discharge to any adjacent metallic substance.*

Transformers, &c., on consumers' premises. 43. *Where transformers are installed within buildings on consumers' premises, they shall be contained in a fireproof chamber securely locked, and the high-pressure service lines in highly glazed porcelain tubes bedded in chases cut in brickwork or masonry.*

Testing consumer's wires for leakage by Undertakers. 44. If the Undertakers are reasonably satisfied, after making all proper examination by testing or otherwise, that a connection with the earth exists at some part of a circuit of such resistance as to be a source of danger, and that such connection does not exist at any part of the circuit belonging to the Undertakers, then and in such case any officer of the Undertakers, duly authorised by them in writing, *or, if the Undertakers so require, an electric inspector*, may, for the purpose of discovering whether such connection with the earth exists at any part of a circuit within or upon any consumer's premises, at all reasonable times, after giving one hour's notice of his intention to do so, enter any such premises and disconnect the consumer's wires from the service lines, and may require the consumer to permit him to inspect and test the wires and fittings belonging to the consumer and forming part of the circuit.

In any case where the Undertakers require the services of an electric inspector under this regulation they shall pay him the prescribed fee.

Supply to be discontinued if leakage exceeds a certain limit. 45. If on such testing the officer or the electric inspector discovers that a connection exists between the consumer's wires and the earth, and that such connection has an electrical resistance not exceeding 5,000 ohms, or if the consumer does not give all due facilities for such inspection and testing, the Undertakers shall forthwith discontinue the supply of energy to the premises in question, giving immediate notice of such discontinuance to the consumer, and shall not recommence such

Digitized by Google

supply until they are reasonably satisfied that such connection with the earth has been removed.

Provided that in cases where the maximum power taken by any consumer exceeds 25,000 watts, the consumer's wires may be divided for the purposes of this testing into separate circuits, the insulation resistance of each of which shall exceed 5,000 ohms.

Appeal to electric inspector. 46. If any consumer is dissatisfied with the action of the Undertakers either in discontinuing or in not recommencing the supply of energy to his premises, the wires and fittings of such consumer may, on his application and on payment of the prescribed fee, be tested for the existence of connection with the earth by an electric inspector.

This regulation shall be endorsed on every notice given under the provisions of the last preceding regulation.

VII.—Arc Lighting.

Arc lamps to be guarded. 47. *All arc lamps shall be so guarded as to prevent pieces of ignited carbon or broken glass falling from them, and shall not be used in situations where there is any danger of the presence of explosive dust or gas.*

Height from ground. 48. *Arc lamps used in any street shall be so fixed as not to be in any part at a less height than 10ft. from the ground.*

Cut-off switch. 49. *A cut-off switch, fixed in a suitable locked receptacle, shall be provided for every high-pressure arc lamp, and such switch shall be of such pattern and construction as will provide :—*

(a.) *That the lamp can by its means be entirely disconnected from the supply circuit;*

(b.) *That the switch itself can be safely operated in the dark by an inexperienced person and without special precautions ; and*

(c.) *That there shall be no danger of any injurious electrical arcing, sparking, or heating being caused by the operation of the switch.*

Penalties.

Penalties. 50. If the Undertakers make default in complying with any of the preceding regulations, they shall be liable to a penalty not exceeding £10 for every such default, and to a daily penalty not exceeding £10.

The imposition of any penalty under this regulation shall not affect the liability of the Undertakers to make compensation in respect of any damage or injury which may be caused by reason of such default.

B.—REGULATIONS AS TO SUPPLY.

Notice of intention to supply through mains. 1. One week at least before the Undertakers are ready to commence to supply energy through any feeding, charging, or distributing main, they shall serve a notice upon the local authority of their intention to commence such supply.

Undertakers to provide constant supply. 2. From and after the time when the Undertakers commence to supply energy through any distributing main, they shall maintain a supply of sufficient power for the use of all the consumers for the time being entitled to be supplied from such main ; and such supply shall, except so far as may be otherwise agreed upon from time to time between the local authority and the Undertakers, be constantly maintained. Provided that, for the purposes of testing, the authority by whom the electric inspector is appointed may give permission to the Undertakers to discontinue the supply at such intervals of time and for such periods as it may think expedient, and that for any other purposes connected with the efficient working of the undertaking, the Undertakers may, with the permission of the Board of Trade, discontinue the supply at such intervals of time and for such periods as the Board of Trade may think expedient. Where the supply is so discontinued, notice of such discontinuance, and of the probable duration thereof, shall be forthwith served upon the local authority.

Provisions as regards stoppage. 3. The system of distributing mains shall be so arranged that in case it becomes necessary to stop the supply through any portion of a main for more than one hour, for the purposes of repairs, or for any other reason, the stoppage of supply will in no case exceed in amount a maximum power of 200,000 watts, or extend to the premises of more than 80 consumers, and in the case of every stoppage for more than one hour reasonable notice shall be previously given by the Undertakers to every consumer affected thereby, except in cases of emergency.

Pressure in mains during supply. 4. During the whole of the period when a supply of energy is required to be maintained by the Undertakers in the distributing mains under the Order and these regulations, it shall be maintained at a constant pressure (in these regulations termed the "standard pressure"), to be fixed as hereinafter specified ; but such standard pressure may be different for different portions of the distributing mains. Provided that the Undertakers shall be deemed to have complied with the requirements of this regulation so long as the pressure does not at any point vary more than 3 per cent. from the corresponding standard pressure in the case of a general supply at low pressure, or 2 per cent. in the case of a general supply at high pressure, unless changes in pressure recur so frequently as to cause unsteadiness in the supply.

Fixing of standard pressure. 5. The standard pressure shall be fixed by the Undertakers for every pair of distributing mains, and notice of the amount of such standard pressure shall be given to the local authority before the Undertakers commence to supply energy to consumers through such mains, and such standard pressure shall not be altered except by permission of the local authority, and upon such terms and conditions as the local authority may impose, and after public notice has been given during a period of one month, in such manner as the local authority may require, of the intention of the Undertakers to apply for permission to alter the same. The Undertakers may appeal against any decision of the local authority under this regulation to the Board of Trade, whose decision shall be final.

Declared pressure at consumer's terminals. 6. Before commencing to give a supply of energy to any consumer, the Undertakers shall declare to such consumer the constant pressure at which they propose to supply energy at his terminals. The pressure so declared at any pair of consumer's terminals shall not, except by agreement, be greater than *150* [115] volts or less than 45 volts if continuous, or the equivalents thereof respectively if alternating, and shall not at any time be altered or departed from except in consequence of any authorised alteration of the corresponding standard pressure. In distribution on the three-wire system, the central terminal shall for the purposes of this regulation be considered to form a pair with either of the outer terminals, and similarly for multiple-wire systems ; and, in the case of a transformation of energy on the consumer's premises, the Undertakers shall give the consumer the choice of a supply at either of two different pressures, one of which shall be approximately half the other, and in such case the pressure so chosen by the consumer shall be the declared constant pressure.

Variation of pressure at consumer's terminals. 7. The variation of pressure at any consumer's terminals shall not under any conditions of the supply which the consumer is entitled to receive, nor at any time, exceed 4 per cent. from the declared constant pressure, whether such variation be due to the resistance of the service lines or apparatus belonging to the Undertakers, or to any action or effect produced by such apparatus, for which the consumer cannot be shown to be responsible, or, partly to any variation of pressure in the distributing mains from which the supply is taken.

Penalty for default. 8. If the Undertakers make default in complying with any of these regulations as to supply, they shall, subject to the provisions of the Order, be liable to a penalty not exceeding £5 for every such default, and to a daily penalty not exceeding £5.

These regulations are made subject to the power of the Board of Trade to make such further or other regulations as they may think expedient ; and nothing in these regulations shall be construed to authorise the Undertakers to lay any electric line or work their undertaking otherwise than in accordance with the Order and the principal Act, or to supply energy otherwise than by a system for the time being approved of by the Board of Trade under the Order.

The following are some of the more important of the old rules not to be found in the new :—

Definition of earth. When any casing, support for conductors, conducting wire, or other metallic body is required to be efficiently connected to earth, it shall be deemed to be so connected when it is connected to metallic mains for water supply outside of buildings, or, where these are not available, to a mass of metal having a total surface of at least 4 sq. ft., buried to a depth of at least 3ft. in moist earth, by means of a conductor possessing a mechanical strength, and offering a passage to electrical discharges, equal to that of a strand of seven No. 16 galvanised iron wires.

High and low-pressure conductors laid in proximity. Where any high-pressure conductor is laid within a less distance than 18in. from any low-pressure conductor, or from the surface of the ground, or where any low-pressure conductor is laid within the above-mentioned distance from any previously laid high-pressure conductor, efficient means shall be taken to render it impossible that the low-pressure conductor or the surface of the ground shall become electrically charged by any leakage from or defect in the high-pressure conductor.

Precautions against sparking with high-pressure alternating-current mains. In the case of a high-pressure supply on any alternating-current system, where separately insulated conductors are laid in the same conduit or pass through the same boxes, precautions shall be taken against the discharge of electric sparks between the insulating covering of oppositely charged conductors, by providing a sufficient connection of a conducting nature from one covering to the other throughout.

Aerial Conductors.

Connection of support to earth. Every support, if of metal, shall be efficiently connected to earth, and if of wood or other non-conducting material shall be protected by a lightning conductor fastened to the support along its entire length, and projecting above the support to a height of a least 6in., such lightning conductor being efficiently connected to earth.

Specification of insulation. The material used for insulating any high-pressure aerial conductor shall be such as will not be liable to injurious change of physical structure or condition when exposed to any temperature between the limits of 0deg. and 150° Fahr., or to contact with the ordinary atmosphere of towns or manufacturing districts.

It only remains to point out that the much-discussed old Rule 33, dealing with the thickness of the insulation of high-pressure aerial conductors, although not to be found under *Aerial Conductors*, has not been dropped ; it has merely been transferred, and is now to be found under *General Rules* as Rule 12, where it covers a wider ground.

THE ELECTRICAL TRADE SECTION.

A meeting of the Electrical Trade Section of the London Chamber of Commerce was held on Tuesday, at Botolph House, Eastcheap, Mr. E. Garcké in the chair.

The SECRETARY (Mr. Kenric B. Murray) having read the minutes of the last meeting,

The CHAIRMAN remarked that the principal matter which they had met to discuss was to consider the revised Board of Trade regulations in connection with the supply of electrical energy. He suggested that they should dispose first of the other matters on the agenda. With respect to the Telephone Agreement, he had to report that the Special Committee which been appointed sat on several occasions, and considered many of the suggestions that were submitted to the Section at the last meeting. The Committee was a very representative one, embracing all interests. Needless to say, it was very difficult for the Committee to come to any definite conclusion, and all their decisions were more or less in the nature of a compromise. Sir E. Carbutt and Major Flood Page were requested by the Council to give evidence before the Committee, and had done so.

Mr. SYDNEY MORSE said that, personally, he felt great regret that some gentleman representing purely commercial interests was not sent to give evidence on behalf of the Chamber before the Select Committee. The tendency of the evidence given to the Committee seemed to be very much in favour of the National Telephone Company for what they had done rather than for what they might do ; but if it were not too late, he felt that it would be well for simple commercial evidence to be given.

The CHAIRMAN stated that the point to which Mr. Morse had drawn attention was fully taken into consideration. He himself was not able to attend the Council meeting at which it was discussed, but Mr. Murray informed him that the views expressed by Mr. Morse were strongly put before the Council. He feared it was too late now to submit further evidence, for he believed that the Committee had taken all the evidence. With respect to the question of Light Railways, a Bill had been brought into Parliament by the Government, but he thought from present indications there was very little hope of the Bill passing this Session. Should there be any prospect of that, however, a special meeting of the Joint Committee would be called to consider the position. He did not think that the Bill adequately dealt with the matter. In answer to a question, the Chairman added that the Bill referred to was the outcome of the committee that was appointed, but it was not in conformity with the views expressed by a very large minority of that committee. It might be said to be in accordance with the views expressed by the majority, but a large minority were in favour of legislation on much broader lines. The next matter was that of electric rating, respecting which letters had been received from the Crystal Palace Direct Electric Supply Company (Limited). He had often expressed his views on this subject, but he did not know what they could do in the absence of general legislation. It was rather a large subject for their Section to initiate. The question affected all interests alike, and it was rather hard that the Electrical Section should be left to take the initiative.

Mr. MORSE observed that as electrical companies were in the exceptional position of having only 42 years' tenure, it seemed very hard that they should be subject to the same heavy rating as gas and water companies, which had practically a freehold. It was a large question, but unless some one moved, matters would go on as at present. He hoped that the fact that their section was moving would have some bearing on the question. It would be brought before the Council of the Chamber, who would appoint a committee of all the sections to go into the matter. The rating was not done now on any system, or with the simple idea of doing justice between ratepayers in a particular parish. There was a rating committee composed of interested ratepayers, who did not mind putting up the rating of an electric lighting company. He did not mean to say that they did anything dishonourable, but at the same time it was against all principles of justice that interested parties sh[ould] judge. What he thought the Chamber of Commerce might do was to advocate a central authority for the whole of London, as had been suggested, and with aproper appeal to the High Court of Justice, so that the matter might be dealt with in an impartial manner. Until that was done there would be unsatisfactory rating. The tramway companies, it is true, were on the same lines as themselves, having a limited tenure ; but they had never raised the question as to whether they ought to be put on a different basis from that of gas and water companies. He felt that a central rating authority would be beneficial to the electric lighting companies.

The CHAIRMAN suggested that they should pass another resolution asking the Council of the Chamber to take up the question in a general way, and point out to them the manner in which this matter prejudicially affected the electric light industry.

This was agreed to.

The CHAIRMAN said the next business was to consider a letter which had been received on the subject of electric traction from the National Traction Engine Owners' and Users' Association. After reading the letter, he stated that the point raised had been dealt with in a very competent way, and there was a definite promise from the Home Secretary. On the suggestion of Mr. Morse, it was decided to invite Major Flood Page to meet the Association.

The subject of merchandise marks was afterwards discussed, and Mr. SELLON undertook to act for the Section on the new general Committee, representing all interests of the Chamber, which Mr. MURRAY said it had been decided to appoint.

Mr. MORSE stated that under the Electric Lighting Act of 1888 the Board of Trade inserted in Provisional Orders a power in favour of Local Authorities to purchase electric lighting undertakings at the end of 42 years from the date of the Order. The Board of Trade, however, had this year, as regarded London, inserted 42 years from 1889, which was reducing the period to 35 or 36 years only. The powers of purchase given by the Act of 1888 were not favourable to an electric lighting company, but were favourable to the Local Authority, and it was a compromise by which, when the Act was passed, the Local Authority was given very good terms in return for the right to purchase being exercised at the end of 42 years. This seemed to him a matter in which their industry was very largely interested, and he did not think that the period of 42 years should be reduced without the consent of the company interested. It was quite right that local undertakings should agree with the Local Authority, and that the latter should have the power to purchase at less than 42 years, generally on terms, but where no consent was given by the company it seemed unfair that the Board of Trade should put forward this point, and insist on it. The object of the Board of Trade was to give the Local Authority, whoever that might be, power to purchase all their undertakings at the same date. There was no doubt some good reasons in favour of this, but if so the Board of Trade ought to say that it should only come into operation in respect to companies whose Orders were now being granted on other terms than the terms of the Act of 1888. He did not know how the Chamber felt in the matter, but he thought that a resolution should go to the Board of Trade saying what the electrical industry felt on the subject, and stating that these clauses ought not to go in.

Mr. ERSKINE asked whether the present Orders, apart from those granted this year, were dated from London.

Mr. MORSE replied that every Order granted by the Board of Trade since 1889 included the power of purchase at the end of 42 years from 1889.

It was finally decided that a letter should be addressed to the Board of Trade upon their action in the matter.

The meeting then proceeded to consider the revised Board of Trade regulations.

Mr. ERSKINE said it was very difficult to see by the regulations whether they referred to high or low tension, or both ; and taking the form of "regulations" generally, they seemed to be very badly worded.

The CHAIRMAN said he thought that the matter ought to be considered in detail, and that they should forward a circular to all supply companies asking them to send to the Section their suggestions with a view to their deputing some member of the Section to see the officers of the Board of Trade with a view to getting certain vague points in the regulations cleared up. They might send out these communications at once, and have another meeting next week, when they could go through the various suggestions which they might receive.

Mr. MORSE said he thought they ought to write a letter to the Board of Trade at once, if this course were adopted, and inform the Board what they were doing, and ask them to keep the matter open.

Mr. SELLON, acting on a suggestion from Mr. Morse, undertook to mark the clauses in the regulations which were difficult to understand, and, at the instance of the Chairman, further agreed to make a comparsion between the present and the old form of regulations.

The CHAIRMAN said that they would only regret it hereafter if they did not try now and get the amendments which were necessary.

Mr. MORSE stated that the electric traction protection clauses recommended by the Select Committee of 1893 were not always inserted in private Bills, and he thought it advisable that they should write a letter to the Chairman of the House of Lords, calling attention to the matter. He received a letter a few days ago from a Parliamentary agent, stating that in the South Shields Corporation Bill electric traction was asked for, and that the gas and water companies were opposing it in order to get clauses for their protection. It was sought to make the Corporation answerable "for all accidents, damages, and injuries happening by reason or in consequence of the construction, maintenance, or user of any tramway work, and shall save harmless the Company (that was the South Shields Gas Company), their officers and servants from all damages and costs in respect of such accidents, damages, and injuries." The object of this clause was to make the electrical authority responsible for gas explosions which had occurred and which might occur again. In consequence of this clause he looked into the Bill, when he found that the Telephone Company had a clause which was not in accordance with the clauses of the Joint Committee of the two Houses ; and, further, that the clauses of the Joint Committee were not inserted in the Bill. He afterwards proposed a resolution to the effect that the attention of the authorities should be called to the fact that the traction protection clauses were not always inserted in private Bills giving power for electric traction.

Mr. SHARP seconded the motion, which was adopted, and the proceedings then terminated.

PARLIAMENTARY INTELLIGENCE.

SELECT COMMITTEE ON THE TELEPHONE SERVICE.

Upon the resumption, on Friday last, by the Committee of the House of Commons, presided over by the Postmaster-General, of their inquiry into the telephone service of the United Kingdom,

Mr. JAMES STAATS FORBES, Chairman of the National Telephone Company, continuing his evidence, produced further statistics with a view of testing the reasonableness and truth of the assertions which had been made as to the dearness and want of efficiency of the service afforded by his Company. With a view of disposing of the accusation that the service in Scotland was intolerable, and that the people there could not make use of it, he stated that on one day, namely, April 3rd last, the number of local messages, exclusive of trunk messages, passing through the Glasgow exchanges was 59,020, in the case of which the time occupied in placing subscribers into effective communication was under half a minute; under one minute, 4,590; under a minute and a-half, 974; under two minutes, 698; under two minutes and a-half, 260; under three minutes, 572; under three minutes and a-half, 54; under four minutes, 326; under four minutes and a-half, 218; and five minutes and over, 2,694. The number of messages passing through the Aberdeen exchanges on the same day in which less than half a minute was occupied in placing subscribers in effective communication was 14,050; under a minute 490; under a minute and a-half, 394; under three minutes, 66; and under five minutes, 54. Through the Edinburgh exchanges there passed on the same day 12,130 messages, in the case of which the time occupied in placing the subscribers in effective communication was under half a minute; under a minute, 1,956; under a minute and a-half, 1,298; under two minutes, 1,428; under two minutes and a-half, 628; under three minutes, 1,018; under three and a-half minutes, 110; under four minutes, 250; under four and a-half minutes 34; and five minutes and over, 750. The reasons for delay in making connections were subscribers not answering quickly, others being engaged and junction lines being occupied. Witness also called the attention of the Committee to the fact that on the same day the number of messages dealt with at the Queen Victoria-street exchange in London by one operator in charge of 50 subscribers, during the seven hours from 10 a.m. to 5 p.m., was 176, in which the time occupied in placing the subscribers in effective communication was unedr half a minute; under 1min., 146; under 1½min., 116; under 2min., 20; under 2½min., 34; under 3min., 4; under 3½min., 8; under 4min., 2; and under 5min., 2. Perhaps he ought to explain that each subscriber's call was counted as two messages—the question and the reply.

The CHAIRMAN: Can you give us the number of subscribers at Glasgow, Aberdeen, and Edinburgh?

WITNESS: Glasgow, 5,221; Edinburgh, 1,741; Aberdeen, 1,029; and London, 10,848.

Examination continued: In order to give an idea of the number of local messages passing over the National Telephone Company's system, he would take a few of the more important exchanges:—

Table A.

Exchange.	Number of subscribers.	Total No. of messages per day.	Messages per subscriber.	Cost per message.
				d.
Aberdeen (Central).........	866	11,966	14	0·37
Belfast (High-street)......	932	16,334	18	0·39
Birmingham (Central) ...	1,388	16,463	12	0·53
Blackburn (Central)	558	6,194	11	0·51
Bradford (Swan-arcade)...	1,378	19,685	14	0·44
Brighton (West-street) ...	809	7,062	9	0·70
Bristol (High-street)	681	10,157	15	0·42
Dublin (Dame-street).....	973	8,392	8	0·66
Dundee (Central)	784	15,199	19	0·27
Edinburgh (George-st.)...	407	4,811	12	0·51
Glasgow (Royal)	3,169	39,957	13	0·54
Greenock (Town Hall) ...	402	2,974	7	0·72
Halifax (Central)	312	4,526	15	0·42
Huddersfield (Central) ...	330	7,850	24	0·26
Hull (Central)...............	742	8,870	11	0·51
Leeds (Park-place)	1,574	40,789	26	0·23
Leicester (Central)	539	6,400	12	0·52
Liverpool (Royal)	3,938	96,644	25	0·25
London (Lime-street)......	2,135	22,625	11	1·04
Manchester (Royal).........	2,962	70,952	24	0·27
Newcastle (Quay Side)...	853	6,518	8	0·78
Nottingham (Central) ...	731	10,096	14	0·43
Oldham (Central)	340	3,956	11	0·53
Plymouth (Millbrook) ...	305	3,860	13	0·41
Reading (Central)	327	2,969	9	0·59
Sheffield (Commercial-st.)	2,152	20,652	10	0·48
Sunderland (Arcade)	725	9,096	13	0·47

The WITNESS desired to emphasise the extraordinary user in particular places, such as Leeds, Liverpool and Manchester, which, taken in connection with the efficiency of the call and the price, hardly bore out the swamping assertions which had been made as to dearness and want of efficiency.

The CHAIRMAN: How do you account for the fact that the cost to subscribers per message is so much higher in London than in other places?—Because the telephone is so much less used in London, and is not so essential as in Manchester, for instance.

The CHAIRMAN: Is it also due to the fact that in the City the annual charge is higher?—No doubt.

Mr. BENN: Are we to understand that the greater the business done the less the charge?—That is the direction in which the figures point. The greater the user for a fixed time the less the cost per user.

The CHAIRMAN: In the case of two subscribers paying the same amount, if one uses the telephone more frequently than the other he pays less per message?—Yes.

The CHAIRMAN: May the instances which you have given be taken as fair average specimens of the general state of circumstances throughout the country?—Yes, as nearly as we can ascertain the facts.

Examination continued: As bearing upon the possible effect upon the use of the telephone of a more or less perfect telegraphic service, Witness proceeded to give the following figures in regard to the telegraphic service of certain European countries, together with the ratio per head of the population:—

Table B.

Country.	Population.	Total number of telegrams.	Telegrams per head.
Austria	23,895,413	12,068,064	0·505
Belgium............	6,069,321	5,414,864	0·892
Denmark	2,172,380	1,817,718	0·836
England (United Kingdom)	38,520,116	73,299,237	1·902
France	38,343,192	47,017,117	1·226
Germany	49,428,470	33,172,116	0·671
Holland	4,732,911	4,429,771	0·935
Hungary	17,349,398	6,522,302	0·375
Italy	30,347,291	9,681,912	0·319
Norway	2,001,000	1,740,180	0·869
Roumania	5,040,000	1,649,294	0·327
Russia	120,000,000	13,193,257	0·109
Sweden	4,824,150	2,101,850	0·435
Switzerland	2,917,819	3,838,323	1·3150

The CHAIRMAN: I understand you to suggest that the larger user of the telegraphs probably indicates a more effective telegraphic service, and consequently a less demand for telephonic service?—That is the inference to be drawn.

In the course of his further examination, Mr. FORBES gave statistics showing the number of telephone lines and the population at various centres on December 31st last, from which it appeared that at 73 centres in England and Wales having a total population of 16,632,254, the number of telephone lines was 57,358, giving a population of 290 per line. In 17 centres in Scotland, with a population of 1,607,775, the number of lines was 12,661, and the population per line 127. In five centres in Ireland, having a population of 810,469, the number of lines was 3,319, showing a population per line of 244—making a grand total for the United Kingdom of 73,338 telephone lines and 19,050,498 population; that is to say, 260 per line. With all the drawbacks to the development of the telephone in this country, we had not made so slight an advance as was sometimes asserted. The conclusion at which he had arrived was that in places of commerce, shipping, and manufactures the service of the National Company compared very favourably with the telephone service at similar places in America. Having laid stress upon the extreme moderation of the initial charges, Witness, dealing next with the the metropolitan local exchanges, mentioned that there were on the Croydon local service, which includes free speaking between Sydenham, Bromley, Redhill, Epsom, and Streatham, 61 subscribers at £10 per annum and 250 subscribers havi[illegible] full metropolitan service; on the Kensington local service there were t[illegible]e subscribers at £10 per annum and 342 subscribers having full metropolitan service; at Kingston, including Richmond and Wimbledon, there were two £10 subscribers to the local service and 36 subscribers having full metropolitan service; on the Battersea local exchange there were one £10 subscriber and 67 subscribers having full metropolitan service; and in the case of the Eastern local exchange there were three £10 subscribers and 279 subscribers having full metropolitan service. The number of private houses connected in the metropolis was 492. Battersea was supposed to be the paradise of the working man, but the figures which he had just given went far to explode the theory that working men desired to use the telephones. As a matter of fact, he did not believe that one working man in a hundred thousand would use the telephone. As to small tradesmen and shop-keepers, although such persons might perhaps have to make use of the telegraph once a-day in connection with their business, they would certainly not subscribe to the telephones. Criticising the estimates put in on behalf of the London County Council for the establishment of a municipal system of telephones, Mr. Forbes pointed out that apparently nothing was allowed for the extraordinary wastage which went on in consequence of people going in for telephones, and then giving them up in a year or two. It was true that the salvage of the instrument and the wire might be left to the Telephone Company, but the cost and labour involved in fitting up the instrument and the wire would be gone, and that might be set down at a waste of from 50 to 75 per cent. This waste had to be paid for, whether out of capital or interest. The Witness next made an elaborate statistical comparison of the National Telephone Company's and the Post Office subscribers. He showed that on December 31, 1894, there were at Newport 271 Company subscribers, as against 85 Post Office subscribers; Barry Dock 607, as against 155; Swansea 262 to 7, whilst at Leicester there were 80 Telephone Company's

Digitized by Google

subscribers in March, 1891, the date of opening, and 524 on December 31, 1894, as against 138 Post Office subscribers in 1885, and 38 at the present time. At Nottingham there were, on December 31st, 918 to the Company's line, which was opened in June, 1881, as against no Post Office subscribers at all. At Derby there were 38 subscribers to the Company's line at its opening in June, 1889, and 387 on December 31, 1894, as against 20 Post Office subscribers at the date of opening, and none at the present time. At Hull the figures were, on January 1, 1891, when the Company's line was opened, 32 subscribers, and on December 31st 713, as against no subscribers to the Post Office line when it was opened in June, 1881, and 52 at the present time, and so on. As to the relations between the National Telephone Company and the Association for the Protection of Telephone Subscribers in London, Witness desired to say that after arriving at the decision that the proposals of the New Telephone Company for working a separate telephone system in London under the conditions set forth in the Agreement between the New Telephone Company and the Association for the Protection of Telephone Subscribers, dated April 25, 1892, could not, with advantage to the public, or with any prospect of financial success to the New Telephone Company, be given effect to, and that in the interests of all parties concerned it was expedient, in order to secure a more efficient service than then existed, to remodel the plant of the National Telephone Company on the metallic circuit principle, negotiations took place between the representatives of the Association and of the National Telephone Company, with the result that certain assurances which were given by the National Telephone Company, accompanied by certain modifications of tariff, were accepted by the Association as a fulfilment of the obligations of the New Telephone Company to the Association, as set forth in the said Agreement. The assurances referred to were, that the National Telephone Company would continue the work, then in progress, of remodelling its London system upon the metallic circuit principle; and that work had been pushed forward with the utmost vigour, in redemption of the pledges given upon the conclusion of these arrangements.

Replying to questions by Sir Charles Cameron, WITNESS admitted that the telephone system at Stockholm was beyond doubt an excellent one, and the proportion of the subscribers was high. If the same proportion subscribed in London there would be 250,000 telephone subscribers in the metropolis alone.

A question being asked of Mr. Forbes relating to an agreement with the Mutual Telephone Company, of Manchester, WITNESS declined to answer it or to put in the Agreement, on the ground that in the event of future litigation such evidence might be used to the prejudice of the National Telephone Company.

The Committee deliberated for some time in private as to the course they would adopt in view of this protest, but eventually adjourned until Tuesday without announcing any decision upon the point.

TUESDAY, MAY 28TH.

Mr. J. S. FORBES, Chairman of the National Telephone Company, was further examined. He now withdrew his objection to the production of the Agreement between the Mutual Company of Manchester and the New Telephone Company, and laid it before the Committee. In answer to Sir Charles Cameron, he said that the New Company bought out the Mutual, and it remained the property of that Company, but the National Company possessed nearly all the shares, and had control. The New Company was in process of liquidation. The Post Office and the Company might be in arbitration some day or other, and it might not suit to reveal too much. He proceeded to show on what standing the companies had been merged. The companies were the National, the United Telephone Company, the Lancashire and Cheshire, the Northern District, the South of England, the Western Counties and South Wales, Sheffield Telephonic Exchange, the Caledonian, Universal, Isle of Man, Telephone Company of Ireland, Thanet Company, and the Home Telephone Company. The stocks of the first three companies were cancelled, and new stocks given in exchange. They were amalgamated on the basis of the market value of the day. Taking all the companies, the money spent in construction was £1,813,000, the amalgamation purchase value was £3,105,000, and what some might call water amounted to £1,292,000. Since the companies had been amalgamated under the National, beginning with 1890, up to the end of December, they had spent in sovereigns £1,459,000, which, with the value above given, represented £4,565,000. An agreement for mutual working without rivalry, and for inter-communication between the systems was made with the New Company, represented by the Duke of Marlborough, in July, 1892. Afterwards the National acquired the undertaking. A great many of the people in the New Company exchanged their shares for shares in the National Company, but those who preferred it got cash. £750,000 was the amount.

Sir CHARLES CAMERON: My point is this. We assume that it stands at £750,000 in your books. That is unproductive capital is it not?

WITNESS: There was the Manchester business, which was a service very well laid out.

Sir CHARLES CAMERON: Manchester cannot bear any material part of the £750,000. It was £60,000, so that a large part must be unproductive capital.

WITNESS: You lose sight of the fact that we have gone on spending money for these improvements in London, which, if we had not done, they would. It is cheaper to have done this thing and better for our subscribers than to have a company in London in competition with us. That is how I defend this transaction.

Mr. BENN asked if it was not where competition has reached a fair point that the rates have been reduced.

WITNESS: Yes, for the time being. But you must not lose sight of the fact that if competition goes on that must be covered, and the price in the end will be higher. He looked upon it as absurd to suppose that Great Britain could be accommodated with the telephone to the extent of 50,000 subscribers for an amount under £2,000,000. The figures he had given did not support that construction.

Sir JAMES FERGUSSON: Your licence ceases in 1911; but how long would it avail to go on and meet the requirements of the public?—As long as any man could make up his mind to spend money on a continually decreasing tenure.

The day might come—and possibly in nine years—when it would not be remunerative to you to expend your capital?—Not remunerative to anybody on the tenure. If we had 25 years to run instead of 16, or 42 instead of 25, the question of price assumes a totally different aspect. At first the development of the Company was extremely hindered. If the Company had had the means and the facilities here in London under the law they could have developed their system much more economically, much more rapidly, and could have supplied customers on a lower annual charge. In some respects expenses advanced with increased subscriptions, and in some respects they did not. When they reached a particular level of subscribers in an area up to a certain point the more subscribers the better, because they diluted the fixed charges, but beyond that number there might be expenses which would make the cost of subscribers high. Happily, this condition of things, when the addition of subscribers would tell the other way, had not yet arrived. The Company's interest would be for some time to go on developing business as rapidly as possible.

Mr. A. C. MORTON, M.P., was interposed as a witness at this point, Mr. Forbes' further examination being suspended. Mr. Morton laid before the Committee the report drawn up by Mr. H. Montague Bates, chief clerk to the Commissioners of Sewers of London, upon the replies to a circular issued to telephone users in the City, asking their opinion as to the efficiency and the cost of the existing service. The circular was issued to 3,450 subscribers to the National Telephone Company, being, as far as was ascertained, the whole of the users in the City, and answers were requested to two questions:—(1) "Do you, as subscriber to the National Telephone Company, consider their service efficient? If unsatisfactory, state in what respects." (2) "What is your opinion as to existing charges?" The replies received were 1,055. The opinion of the majority as to the inefficiency and costliness of the service confirmed in every particular the evidence given by the Chairman of the Streets Committee, Mr. George Berridge, and Mr. Bates before the Select Committee.

Mr. BEVERIDGE, of Glasgow, gave evidence as the telephone service in that city. There are 4,791 users, but 382 have more than one telephone, and this reduces the actual number of subscribers to 4,409. Petitions had been exhibited in public places for signature in reference to the nature of the telephone service. Out of 1,018 signatures, 970 were those of persons who regarded the service in Glasgow as inefficient, inadequate, and too expensive.

Mr. TULLY: You stated that there is £1,292,000 watered capital?—It is water, but there is a good deal of spirit in it.

To pay a dividend of 5 per cent. on that would require £64,000 a year; so each telephone subscriber, in order to enable you to pay this £64,000 a year, has to pay an increased price necessarily for his telephone?—Well, that is a proposition I do not know.

Where do you get the money to pay that?—It is in the subscription.

Doesn't it follow from what I say that it has to be charged in a certain proportion?—Yes, it has; and any people who propose to found another company will find themselves in the same position.

Mr. TULLY put the case of the Glasgow Corporation as a body that might maintain a telephone service with advantage.

Mr. FOBES said the Corporation would have to charge a paying rate. He did not know what corporations might do; but he did not think they were more far-seeing or able than companies. If they could start a telephone system without paying for it, of course it would be a very good thing to do. It would be of extreme advantage to the people who could afford to pay; but it would be a great hardship upon the inhabitants of Glasgow who would not and could not use the telephone. It would be a grievance to the great body of the people of a city if these cheap rates were to be brought about by corporations making use of the rates, or appropriating money in their keeping, because it would be expended for the benefit of merchants, manufacturers, and such people, who used the telephone and could well afford to pay a great deal more than they did.

Mr. TULLY: But the public are already paying through loss of business to the Post Office?—That is not my point. If the rates of a city are saddled with the expense of supporting the telephone service, it will benefit the tradesmen, merchants, financiers, and such people, who can afford to pay.

In reply to Mr. Snape, WITNESS said that the average of working expenses, £6. 4s. 7d., included the whole cost of working and maintaining the lines from day to day as a going concern, including the up-keep of material. They did not include debentures or interest on capital. Out of the receipts, 62 per cent. was working expenses. There was a very large amount for wayleaves. If municipalities had the telephones, they would not have to pay for the streets; but they would for wayleaves over private property. The Government would not have to pay royalty; but it might give a service at a price below its value to users of the telephone at the expense of the masses, who did not want the telephone. The people who would be benefited by such a change had ten times more value than their present subscription. He undertook to say that the bulk of new subscribers came from the increased knowledge of the value of the telephone, and not from the reduced price.

Mr. LAMB, of the Telegraph Department of the Post Office, was recalled, and gave evidence mainly in rebuttal or criticism of statements by other witnesses. He stated that in Germany there is a single-wire system throughout. France was now opposed to a reduction of rates in its service, and a recommendation to that effect had just been adopted by the Budget Committee. In Italy the law forbade telephone competition, but it was allowed in Rome, which had it before the law was passed. The

Digitized by Google

reason was that competition was believed to be detrimental to the public service. Both in Norway and Sweden an additional charge was made for telephoning a message to a post office for transmission as a telegram. In Switzerland an increase of charge would be made in the case of persons who had 800 conversations or over per year. Gen. Webber had estimated that £17 would not be an unreasonable charge in the City of London for subscribers who wished to communicate with all the others; but in his estimate he had made no provision for junction wires between the exchanges. The fact was that the Duke of Marlborough in his plans had desired that the Post Office should supply junction wires for London generally. The estimates of cost for these were £178,000, and for the City proper about half, or £89,000. That capital expenditure was not included in Gen. Webber's estimate. This did not apply to the other estimates on behalf of the London County Council. He did not regard conduits as suitable for telephone wires, and that was also the opinion of Mr. Preece. The lines would be in many cases absolutely under all the conduits of the electric lighting cables. Gen. Webber had also assumed that there are 28,000 subscribers in the City. But there are only 27,827 separate tenancies in the City, and if the Middle Temple were included it would bring the total to 29,000. He did not approve of taking over the business in such a way that depreciation or loss would ensue to the general taxpayer, and prudence pointed to the maintenance of rates at a fair point which would afford a certainty of some profit. While he hoped that some day the telephones would be in the hands of the State, he thought it would be impossible to reduce the rates. If done at all it should be done on the ground of actual experience and not on the ground of mere estimate. He agreed with Mr. Preece's estimate as to the cost of laying down a system in London. It was an estimate based on practical experiment, and far more reliable than the estimates of gentlemen of no practical experience in carrying out such work. Everywhere competition in this service was giving way, and the tendency was to have one system. The telephone is in the hands of the State in France, Germany, Austria, and Belgium, and the State is acquiring possession in some other countries.

This concluded the evidence tendered before the Committee, which has now to consider its report.

CORRESPONDENCE.

PRESSURE CURVES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I observe among the records of electrical pressure which are published in the current number of *The Electrician* one relating to the Kensington and Knightsbridge Company for March 20th. Mr. Swinton placed his recording voltmeter in my laboratory on March 19th and 20th. On the 19th I purposely suspended my work, and took no more current than sufficed for domestic purposes, but on the 20th, at 10 p.m., I took a rather heavy current for a quarter of an hour, during which period my magnetic cut-out flew two or three times. There was in consequence a drop of about four volts, chiefly on my service connections. I think it is due to the supply company to point this out, because a drop of four volts is quite unknown in this district. I do not know what goes on in the daytime, but after dark even a two-volt variation, sufficiently quick to produce a perceptible flicker, is very rare.

These variations probably arise chiefly on the mains, due to changes of distribution of load, and are not perceptible at the feeding points. My house is midway between three feeding points and halfway between two batteries, but one of these had been destroyed by the fire at Kensington Court. The average pressure on March 20th, between 10 and 11 p.m. was between 100·5 and 101 volts, as measured by Clark cell and potentiometer.

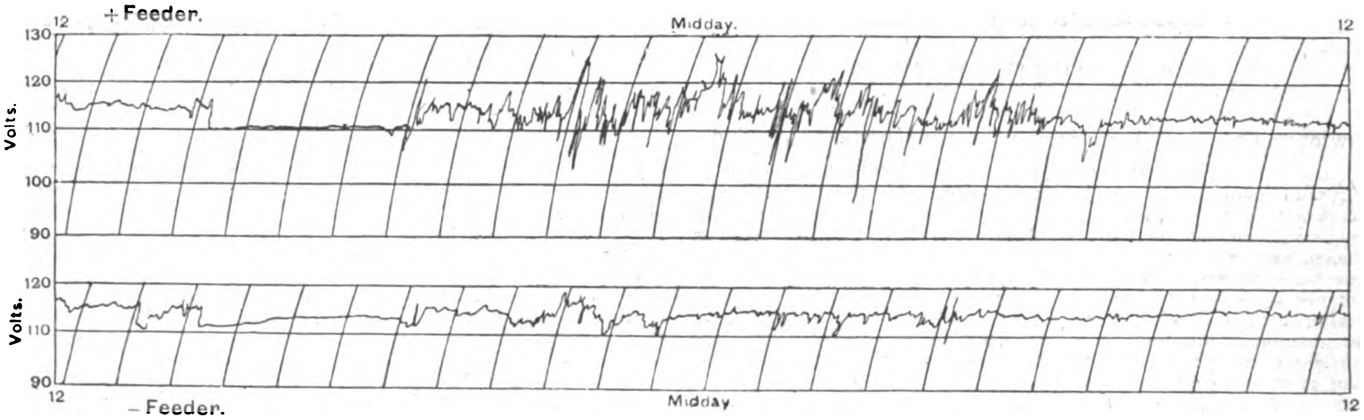
Mr. Swinton has evidently sent you the record for the 20th instead of the one for the 19th inadvertently, as I called the attention of his assistant to the matter at the time.—Yours, &c.,
A. P. Trotter.

28, Victoria-street, Westminster, London, S.W.
May 29, 1895.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Will you kindly allow me to point out that the diagram published in this week's *Electrician*, showing the electrical pressure maintained by the St. Pancras Vestry, is not correct, and does not truly represent the pressure for the 24 hours of May 2nd. In the first place the diagram represents us with batteries on the circuit from 3:30 till 7:30 p.m., and then a very varying pressure from 7:30 p.m. till midnight. The batteries were actually only supplying current on this day from 3:30 till 7:30 a.m., and the irregular line shows the pressure during the morning, when very few lamps were alight, the load consisting almost entirely of motors. The diagram showing the pressure from midnight till midday much more nearly represents our pressure for the other 12 hours of the 24; but even in this case we cannot accept as correct the pressure which is credited to us during the evening since on referring to our own recording voltmeter cards for May 2nd, showing the voltage at the feeding point adjacent to Fitzroy-square, we find that a steady pressure of 112 to 113 volts was maintained throughout, and further that these figures are confirmed by the readings of the voltmeters on the switchboard. Feeling that we have been misrepresented in the diagram, I shall be glad if you will insert this in your next issue, in order that our actual voltage may be better understood.—Yours, truly,
T. Cooper, Assistant Engineer,
Vestry of St. Pancras.

[We have pleasure in publishing two official pressure curves, taken on the same day of 24 hours, and at nearly the same point, as that taken by Mr. Swinton. That there is a succession of very considerable differences between the pressures on the two sections—the positive being markedly irregular in the morning, while the negative is nearly steady—is due to the fact that almost the whole of the motor load carried by the St. Pancras mains occurs on the positive section.—Ed. *E.*]



Pressure Curves taken from St. Pancras Mains at Fitzroy Square, May 2nd.

THE BOARD OF TRADE AND THE ELECTRIC LIGHTING ACTS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I am very glad to see your head-note upon the question put in the House of Commons last Monday.

It may be reasonable for the Board of Trade to determine that the power to purchase all London Orders shall arise at the same time. But it was the intention of Parliament that the special terms of purchase under Section 2 of the Act of 1888 should only arise at the expiration of 42 years from

Digitized by Google

the grant of the Order in question. And I contend that the Board of Trade have no right to say that an undertaking under the Electric Lighting Acts shall be compulsorily bought at the end of a shorter period upon the statutory terms, unless the undertakers make an agreement to the contrary with the Local Authority.

In the case of my Company—on whose behalf the question was put in the House—we had an unconditional consent from the Local Authority.—Yours, &c., SYDNEY MORSE.

4, Fenchurch-avenue, E.C., May 24, 1895.

ELECTRICAL TERMINOLOGY AND GREEK PARTICIPLES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In answer to the trenchant and incisive letter of Mr. Portheim, which appeared in your issue of March 15th, in reply to my protest against the use of the word ka*th*ion, I beg to state that I was not forgetful of the existence of the Greek verb *καθίημς*, and am also aware that there are the present participle *καθίεις* and the aorist participle *καθέις*, but had not been informed of any participle *καθίωγ*, nor on consulting the grammar and dictionary at my disposal have I been able to find it.

If, however, Mr. Portheim *can* quote a passage from Greek literature in which this participle occurs, I should still consider that the word *ion* was originally intended as a derivative of *εἶμς* rather than of *ἵημς*, for otherwise the aspirate would be represented in English, and we should hear of *hions* instead of *ions*, in the same manner as we have *hysteresis*, and not *ysteresis*.

What is meant by "we surely consider the *kathion* in the light of a *carrier of ions* to the kathode" I am incapable of understanding, since I always considered that the kations are the ions *separated* at the kathode, and not the *carriers* of *ions in general*.

If Mr. Portheim will refer to the early electrical literature in which the ion separated at the kathode is mentioned, I feel certain that he will find that ka*t*ion is the term employed, and that his phrase, "good old kathion," is a misnomer.—Yours, &c.,

Royal Military College of Canada. JOHN WADDELL.

LEGAL INTELLIGENCE.

Fowler v. the Chelsea Electricity Supply Company (Limited): Landon and Others v. the Same.

In the Chancery Division on Friday, the 24th inst., these actions came before Mr. Justice North on motion for interlocutory injunction. The first action is brought by the tenant of a flat at No. 75, Cadogan-gardens, Chelsea, and the second by the landlord and tenants of other flats in the same house to restrain the defendant Company from continuing an alleged nuisance occasioned by noise and vibration.

After some discussion it was arranged in each case that the motion should stand till trial, the writs to be treated as statements of claim, the defendants to deliver statements of defence within 14 days, and leave being given to have the trials expedited.

Muirhead v. the National Electric Supply Company (Limited).

An action brought by Mr. John Muirhead against the National Electric Supply Company, to recover Director's fees for three years, came before Mr. Justice Day, in the Queen's Bench Division, on Friday, the 24th inst.

It appeared that the defendant Company carried on business as an electric lighting company at Preston, and the case for the plaintiff was that he became a Director of the Company in 1891, and continued on the board till 1894, and now claimed to be paid for his services during that period. The 107th clause of the Articles of Association of the Company provided that the remuneration of the Directors should be £200 per annum for the Chairman, and £100 for each of the Directors, together with such other sum, if any, as should be voted by the Company in general meeting. A clause of the Memorandum of Association fixed the rights of the Founders' and Ordinary shares, and then stated, "There shall then be set aside out of the profit of the Company such percentage thereof as shall from time to time be appropriated by the Articles of Association for payment of Directors' remuneration." It was contended for the plaintiff that the meaning of the clause was simply to apportion the profits as between the different classes of shareholders, and did not preclude any payment to the Directors until such profits had been made. The Company, as a matter of fact, had made no profits at all, but it was submitted that the Directors were entitled to be paid out of any funds that remained.

On behalf of the defendants, it was contended that by the true construction of the Memorandum of Association provision was made for setting aside out of the net profits such percentage as should from time to time be appropriated by the Articles of Association as remuneration to the Directors. The Directors were only to be paid out of the net profit, and there was no provision whatever in any of the documents which indicated that they were to be paid out of capital.

At the conclusion of the arguments of counsel his Lordship gave judgment for the defendants, but granted a stay of execution, with the view to an appeal.

Walsall Electric Company v. Walsall District Iron Company.

The plaintiffs recently brought an action against the defendants for the sum of £64. 16s. 11d., balance due for work done in connection with the putting down of an electric lighting installation at the defendants' works. The defendants contended that there had been a complete breakdown of plant, to which the plaintiffs replied that whatever irregularities there might have been were due to want of care on the part of the persons employed by the defendants to superintend the working of the plant. A settlement was ultimately arrived at between the parties.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price, 7s. 6d., post free 8s. 3d., abroad 9s.

The following New Books and Editions of "THE ELECTRICIAN" SERIES *can be obtained of the Booksellers or direct from the Publishing Offices:—*

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett. Strong portfolios can be had, price 1s. each. A full prospectus can be obtained post free.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

A LARGE-SHEET TABLE, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 3s. 6d.; Unvarnished, 3s. —each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

"THE ELECTRICIAN."—A special notice concerning certain changes in the price, &c., of this journal will be found on page 158.

TENDERS INVITED.—The Electric Lighting Committee of the Huddersfield Town Council invite tenders for cables, transformers, switches, fuses, and covers for their electric lighting works during the ensuing 12 months. Tenders to be into Mr. A. B. Mountain, Andrew's-road, Huddersfield, by to-morrow (Saturday).

——— By command of the Postmaster-General, tenders are invited for the purchase of about 35 tons of old copper (wire, plates, &c.) and quantities of other metals, india-rubber covered wire, &c. Forms of tender can be obtained of Mr. Charles E. Stuart, Controller of Stores, General Post Office, Telegraph-street, E.C., and tenders must be sent in not later than 10 a.m. on Monday, June 17th.

——— *Extension of Time.*—The time for sending in tenders for the supply of electric light lamp pillars and copper canopies required by the Corporation of Brighton has been extended until 10 a.m. of Saturday, June 1st.

——— Tenders are being invited until June 29th by the Municipal Authorities of Braila, Roumania, for the concession for the lighting of the public streets either by electricity or gas.

——— The North-Eastern Railway Company invite tenders for telegraph apparatus, telegraph wires and line stores. Tenders, addressed to the secretary (Mr. C. N. Wilkinson) must be in by June 10th.

Digitized by Google

TENDERS INVITED.—The Godalming Town Council invite proposals for the installation of the electric light for public and private lighting within the borough.

——— The Italian military authorities at Pavia are inviting tenders for the supply of 105,600 metres of rubber-covered telegraph wire 1·6mm. in diameter.

——— Tenders are invited by the General Direction of the Roumanian Posts and Telegraphs at Bucharest until June 15th for the supply of 4,000 Callaud cells for telegraphic purposes."

TENDERS ACCEPTED.—The Public Library Committee of the Worcester City Council, at their last meeting, discussed the report of the Sub-Committee appointed to consider tenders for the supply of fittings for the electric light in the Institute. The Committee recommended the acceptance of the tender of Messrs. Graham and Biddle, Oxford-street, London, for the sum of £768. After some discussion, however, it was decided to accept the tender of a local firm, the New British Electrical Installation Contractors, amounting to £849.

——— The Hanley Town Council have accepted the tenders of Messrs. W. H. Allen, Son and Co., for the supply of a condenser for their electricity works, for the sum of £755, and the tender of Messrs. H. and T. Danks, for boilers, &c., for £1,050.

——— The tender of Messrs. Baily, Grundy and Barrett (Limited) for carrying out the work in connection with the installation of electric fire brigade calls and street posts has been accepted by the Cambridge Town Council. The work is to be carried out from plans prepared by Mr. A. Barrett.

TENDERS RECEIVED.—The Electric Lighting Committee of the Chester City Council some time ago submitted to Lord Kelvin six tenders received for the lighting of the city for his consideration and report, and the Committee have now decided to recommend the tender of Thomas Parker (Limited) for acceptance.

SALE BY AUCTION.—Messrs. Wheatley Kirk, Price and Goulty will sell by public auction at the Mart, Tokenhouse-yard, London, E.C., on Thursday, June 13th, at 12:30 for 1 o'clock, the entire valuable property of the Val d'Aosta Syndicate, Limited (in liquidation), consisting of freehold works, mines, &c., with engines, boilers, plant, railways, water rights, &c., of which particulars are given in our advertisement columns. The plant is in first-class condition, and is especially suitable for carrying on the trade of copper depositing, refining, and smelting. This sale offers an exceptional opportunity for capitalists, as the works, plant and patent rights are practically sold as a going concern. The auctioneers, Messrs. Wheatley Kirk, Price and Goulty, of 49, Queen Victoria-street, London, E.C., and Albert-square, Manchester, will supply plans and descriptive particulars gratis, as will also the liquidator, Mr. F. R. Reeves, Mansion House-buildings, E.C., the solicitors, Messrs. Deacon, Gibson and Medcalf, 9, Great St. Helen's, E.C., and Messrs. Mackrell, Maton, Godlee and Quincey, 21, Cannon-street, E.C.

APPOINTMENTS VACANT.—The Liverpool Salvage Association require a practical engineer to act as superintendent of steam pumps, electrical installations, &c. Salary, £150 to £200 per annum. Applications to the Chairman, A 20, Exchange-buildings, Liverpool, by June 10th.

——— The Victoria Institute Committee of the Worcester Corporation require a science master. Salary £200 per annum. Applications to the Secretary by June 4th.

BUSINESS FOR SALE.—Mr. John M. Macleod, C.A., of 101, St. Vincent-street, Glasgow, has for disposal the old-established business of electrical engineers, bell hangers, &c., carried on by Mr. J. Scott, under the style of D. and G. Graham, at 130 and 140, Douglas-street, and Byars-road, Glasgow, together with the whole of the stock-in-trade, plant, machinery, &c. Offers must be sent in to Mr. Macleod by June 7th. Some further particulars appear in our advertisement pages.

APPOINTMENT.—Prof. W. T. A. Emtage, M.A., has been elected principal of the Wandsworth Technical Institute, at a salary of £350 per annum. The appointment is subject to the approval of the Technical Education Board of the London County Council. Prof. Emtage is at present Assistant Professor of Mathematics and Physics at the University College, Nottingham.

LIQUIDATIONS.—It was resolved on April 9th (the resolution was confirmed on April 24th) that T. L. Hemming and Co. (Limited), of 88, Snow-hill, Birmingham, be voluntary wound up. The assets and property of the Company have been sold to Hemming and Co. (Limited). Mr. S. Wright, C.A., 39, Corporation-street, Birmingham, has been appointed liquidator of the old Company.

——— A meeting is to be held at the office of Mr. W. E. Young, 26, Athol-street, Douglas, Isle of Man, on June 24th, at 11 o'clock, for the purpose of receiving an account of the winding-up of the Isle of Man Tramways (Limited).

BANKRUPTCIES.—Notice is given by the trustee (Mr. C. W. Meiter) in the bankruptcy of George Frederick Rogers, electrical engineer, of 5, Great Winchester-street, London, E.C., that creditors who have not yet proved their debts must forward proofs to him forthwith.

——— Notice is given that all claims in the separate estate of C. W. W. Young (late of Young and Buss, electric bell manufacturers, 18, Blantford-street, London, W.) must be sent in to Mr. H. W. Figg, 37, Upper Thames-street, London, E.C., by June 6th.

——— The creditors in the failure of the Ford Lloyd Manufacturing Company (Limited) include the following :—

	£	s.	d.
C. Atkins and Nisbett, London	£19	19	3
Johnstone, Benjamin and Co., London	28	2	3
Le Carbone, London	17	19	3
Summerling and Co. (Limited), London	58	0	0
Wells, Gallimore and Taylor, Birmingham	17	2	0
W. Wood and Co., Burslem	39	0	0
C. T. Maling and Sons, Newcastle	21	17	2

——— Notice is given of the release of the trustee (Mr. R. Sands) in the bankruptcy of Wm. Andrews, electrician, of 6, St. Anne's Valley, Nottingham.

ELECTRO-HARMONIC SOCIETY.—The annual general meeting of this society takes place to-day (Friday) at 4:30, at 28, Victoria-street, Westminster, London, S.W., to receive the annual statement of accounts, &c.

CATALOGUE.—The Willans engine is going ahead in America, and it seems not unlikely that the tardy conversion of our transatlantic cousins to high-speed practice will be followed by as universal an adoption of the central-value engine in the States as it has received in our country. We have just received a Catalogue, issued by the Bullock Manufacturing Company of Chicago, of the "central-valve" Willans engine. This firm is widely introducing the Willans engine in America. The Catalogue is admirably illustrated and bristles with information. There is a large photo of a 650-I.H.P. triple-expansion condensing Willans engine, which is now in use at a Lancashire cotton mill, and which should silence the objections of those who assert that the high-speed "central-valve" engine is not adapted to large powers. It is evident from the material compiled in this Catalogue that, at any rate as far as high-speed practice is concerned, the Americans are not above learning lessons from English engineers; and they are wise, for our experience of this class of engine has been eminently satisfactory.

TELEPHONES.—The Electrical Company (Limited), of 122 and 124, Charing Cross-road, Oxford-street (London, W.C.), send their latest list of telephones of various patterns, and telephonic apparatus and accessories. The list is fully illustrated, and contains clear diagrams of connections, prices, &c.

AGRICULTURAL HALL (LONDON, N.).—The electric lighting of the Royal Military Tournament at the Agricultural Hall, Islington, N., was carried out by Messrs. Bergtheil and Young. This is one of the few occasions in which an attempt is made to light the hall effectively by electricity. The private electrical installation of incandescent lamps for the Tournament is being supplied from dynamos and direct coupled gas engines of the Dawson Company's high-speed type.

AYR.—The Town Council, at their meeting on Monday, decided to extend the electric mains round by Miller-road and Alloway-place at an estimated cost of £700.

BATH AND WEST OF ENGLAND SHOW.—The annual show of the Bath and West and Southern Counties Society, opened at Taunton this week, proved a great success. Amongst the exhibitors are Mr. E. S. Hindley (who shows engines, pumps, dynamos, motors, circular saws, &c.), Messrs. Clayton and Shuttleworth (portable steam and petroleum engines, each fitted with all the most recent improvements), Crossley Bros. (gas and oil engines, large and small, including a special high-speed electric light engine of 20 I.H.P., fitted with special governing arrangement), John Fowler and Co., Leeds (portable engines), Marshall, Sons and Co. (portable engines, &c.), Ransomes, Sims and Jefferies (portable and fixed engines and boilers, and Ransome's force pump for the efficient cleaning out of traction and portable engines), Willcox and Co. (engineers' stores, tools, pumps, oil filters, &c.)

BATTLESHIP LIGHTING.—It is stated that at the forthcoming visit of the English Channel squadron to Kiel the electric lighting of the vessels will be out of the usual order. It is intended to light up the whole of the upper decks and the superstructures by incandescent lamps, and use a number of coloured lamps for the masts, stays, &c. The illuminating arrangements are to be under the supervision of Lieuts. Fraser and Carey, of the "Royal Sovereign" and "Empress of India."

CLUB LIGHTING.—The new Borough Club, Nottingham, is lighted throughout by electricity. The installation has been carried out by Mr. Joseph Blackburn, Gresham Works, Nottingham.

Digitized by Google

COWES (I.W.).—The District Council have appointed Mr. F. H. Medhurst as electrical expert, to advise them in their scheme for lighting the district electrically, at an inclusive fee of 25 guineas.

DURBAN.—Mr. W. H. Preece, together with Mr. James Fletcher, the borough engineer, have prepared and presented exhaustive reports dealing with the question of the best of two schemes for lighting Durban by electricity. The proposal of the borough engineer is the utilisation of the steam plant in combination with sewage disposal works, and this scheme, with certain modifications, has Mr. Preece's recommendation. It is proposed that plant should be put down with capacity for supplying 60 2,000-c.p. arcs and 2,500 16-c.p. incandescents, with room for additional power when required. It is proposed to borrow £25,000 for the purposes of the scheme, and an annual income is estimated at about £9,000. It is proposed that a maximum of 1s. per unit should be charged for current, which it is hoped to reduce soon after the scheme is in working order. Mr. Preece further recommends that plans and specifications be prepared and tenders invited from all the great manufacturing firms in Great Britain, who should be requested to submit particulars of their various systems. In the borough engineer's scheme it is strongly recommended that all wires be placed underground. The report is to be considered at an early meeting of the Town Council.

EDINBURGH.—The Electric Light Committee having received an extensively signed requisition from the inhabitants of Stockbridge requesting an extension of the electric mains for private lighting to the Water of Leith Bridge, and having received the requisite guarantee in the matter have resolved to approve the scheme, which is estimated to cost about £1,200.

ELECTRIC MOTIVE POWER IN WEAVING MILLS.—Messrs. J. and J. Cash, of Kingfields, near Coventry, have recently placed an order for electrical plant, with a capacity for supplying current for 40 large looms, each driven by an independent motor. The plant is to be put down in new premises now being built by Messrs. Cash, and the order for the electrical machinery has been placed with the Coventry Electrical Engineering Company.

EXHIBITION.—There is to be an exhibition of railway appliances, &c., at the Imperial Institute, to be opened by Lord Herschell on June 1st, at which Messrs. Krupka and Jacoby will have on show a number of Dr. Lessing's dry batteries, for which they are the agents in this country.

EXHIBITION LIGHTING.—The arc lighting of the Empire of India Exhibition, now being held at Earl's Court, London, is carried out by means of six Brush series dynamos, each designed for 55 lights, and the regulation is effected by Brush-Geipel regulators of the water-resistance pattern. The incandescent lighting plant consists of Mordey alternators of the new type, having a joint capacity of 350 kilowatts. There are also two 75-kilowatt alternators, one direct driven and the other by belt. The exciting plant is in triplicate. The alternator and exciter boards consist of marble panels with the usual Brush switches and instruments. The boards are also fitted with double-pole change-over switches for throwing either of the alternator fields on to the common exciter omnibus bars, or for connecting each alternator to its own independent and direct-driven exciter. The arc-lighting board is arranged for five dynamos and five circuits, with hook and stirrup-pattern switches. The transformers are of the Mordey-Victoria type, having a joint capacity of 276 kilowatts.

GREAT NORTHERN AND CITY RAILWAY.—The Unopposed Bill Committee of the House of Commons on Tuesday passed the Bill which gives to the Great Northern and City Railway Company an extension of time until 1900 within which to construct their authorised electric railway from Finsbury Park to Moorgate-street, City. It will be remembered that an attempt on the part of the Great Northern Company to substitute steam for electricity was rejected by the Parliamentary Committee who considered the proposal.

HAMPSTEAD.—Mr. J. G. Weir, M.P., who lives in the Hampstead district, in forwarding a cheque for the quarter's current for electric lighting of his residence, compliments the Vestry upon the admirable arrangements made for private lighting. Mr. Weir says:—"There is, I think, a very general impression that the electric light is costly; in my experience this is quite a mistake. I have not lost a single lamp since my house has been lighted electrically by the Vestry, and I attribute this very much to the regularity of the current." The Vestry have received similar letters from other leading residents.——At the last meeting of the Vestry, the recommendations of the Lighting Committee that the necessary sub-station, feeder, and distributors for the private lighting of Haverstock Hill, from Belsize-grove to Eton-road, be laid down at an estimated cost of £892, and that a high-tension main for private lighting be laid down from sub-station 6A, in Heath-street, to the corner of Redington-road, at an estimated cost of £294, were approved.

HOPE-JONES ELECTRIC ORGANS.—At a gathering of press representatives and others interested in church organs and organ work, Mr. Hope-Jones gave an interesting explanatory discourse in St. George's Church, Hanover-square, London, W., on Wednesday last. After alluding to the value of the experiments on sound waves by Von Helmholtz, Mr. Hope-Jones explained how he had been working and gradually bringing his electrically worked organ up to its present state of perfection. Amongst the many claims which the inventor makes are: (1) the extreme facility with which the console can be worked; (2) the comparatively small space now occupied by the organ; (3) the readiness with which the console can be moved to any part of the building in which the organ is situate; and (4) the extreme simplicity of the electrical connections. The whole of the work of blowing the organ is practically accomplished by the aid of a small contact disc the size of a sixpenny piece. Mr. Hope-Jones stated that the more recently constructed organs contain features of great service to organists, which it would be absolutely impossible to accomplish with an organ as ordinarily constructed and worked. The cells for supplying current are ordinary Hellesen dry cells, which last from 3 to 12 to 18 months. For working the organ at Hanover-square 1,800 wires are used, and are entirely under the control of the organist. By aid of a new stop switch tone results can be obtained which are described as remarkably effective and musically perfect. The Hope-Jones Company are very busy, having on hand, in addition to many others, a four-manual organ for Worcester Cathedral.

ISLINGTON (LONDON, N.).—In order to anticipate any possible claims for nuisance or vibration from the proximity of the electric lighting works at Eden-grove, the Electric Lighting Committee, at the last meeting of the Vestry, recommended the purchase of three houses close to the station, and after a somewhat ragged discussion the proposal was approved.

KING'S LYNN.—In order that a private company may not obtain powers, at the last meeting of the Town Council a motion was made that the Council obtain a Provisional Electric Lighting Order. After some discussion, however, it was decided to defer consideration of the subject till the next meeting.

KINGSTON-ON-THAMES.—It has been decided to supply all places of worship in this town with electric current at 4½d. per unit net, instead of the usual price of 6d. The Local Government Board have sanctioned the borrowing of £7,772 for electric lighting purposes, to be repaid in 15 years. The original application was for £10,000, to be repaid in 25 years, and a deputation is to wait upon the Local Government Board to urge that the full amount be authorised. The Council have placed an order with Messrs. Siemens Bros. and Co. for the supply of cable for charging electric launches for the sum of £100. With regard to the supply of current for charging electric launches, Mr. Councillor Collings stated that the electric launch was undoubtedly the vessel that would be adopted in future; the demands for these launches was growing every day, and he thought this was sufficient to justify the Council in making arrangements for the supply of current. A satisfactory report has been presented by the Council's electrical engineer (Mr. J. E. Edgcome), which shows a small adverse balance of £76. A satisfactory demand for current is reported, and the success of the Council's scheme is assured. The report has been circulated amongst the members.

LEYTON, ESSEX.—A short time back the report of the Hall Building Committee with regard to electric lighting matters was referred back for further information as to cost, &c., and the committee now report that, having carefully gone into the subject, they are unable to supply any further details, but recommend that tenders be invited and received for the prosecution of the necessary works. The Committee strongly advise that no further delay take place. The hall and municipal buildings would have to be lighted, and the matter was one to be settled at once, and in recommending that the electric light be adopted, although at some additional expense over gas, this addition would be saved in a very short time. It was ultimately decided that the buildings should be wired for the electric light.

LIMERICK.—A correspondent of the *Cork Herald* points out that the electric lighting powers of the Limerick Corporation expire in September, and thinks that the fact of the gas committee and the Corporation being practically identical accounts for the want of enthusiasm displayed by that body in proceeding with the electric lighting order. Several of the leading townsmen are adopting the electric light in place of gas, and Messrs. Baker and Co., electrical engineers, of Sexton-street, Limerick, have, we understand, several large orders in hand.

NORTH STAFFORDSHIRE TRAMWAYS.—A special meeting of the Stoke-on-Trent Town Council is to be held to consider a communication from Mr. Elliott, secretary of the above Company with reference to a scheme for working the trams by electricity.

PROVISIONAL ORDERS.—The application by the Swindon New Town District Council for powers to supply electric current within

Digitized by Google

the Council's district has passed through Committee, and is to be reported to the House of Commons in due course. A similar application by the District Council of Llandudno has been reported. The bill promoted by the Southampton Town Council has passed the Standing Orders Committee of the House. Winchester Corporation's Bill has passed the House of Commons, and only awaits confirmation by the Lords. The Carlisle Corporation Bill has been reported for third reading. Walthamstow has now obtained its Order for lighting the district electrically.

RESEARCH SCHOLARSHIPS.—Mason College, Birmingham, are offering three "Priestley" scholarships in chemistry, two "Bowen" scholarships in engineering, and one in metallurgy, of the annual value of £100 each, for competition. The scholarships are tenable for one year, renewable at the discretion of the Council of the College, and the first award will be made in September next.

RIO DE JANEIRO.—The electric light was recently inaugurated in the extensive locomotive shops of the Central Railway.

SHIP LIGHTING.—Last week a new Cunarder, the "Corinthia," was launched from the yards of the London and Glasgow Shipbuilding Company, of Govan, Glasgow. This is a sister ship to the "Sylvania," lately launched from the same yard. The entire vessel, including all holds, 'tween decks, engine and boiler spaces, and cabins, is lighted throughout with electricity. The electric lighting work has been carried out by Messrs. William Harvie and Co., of Glasgow.

SOUTH AFRICA.—The Johannesburg correspondent of the *African Review* states that nearly every company of importance in that district has now an electric lighting installation. All engine houses, mills, cyanide works, offices, &c., are lighted with 8-c.p. or 16-c.p. incandescent lights, and pit heads, rock houses, &c., with 500-c.p. to 1,000-c.p. arc-lights. The principal manufacturing firms represented are Messrs. Edison and Swan, Woodhouse and Rawson, Siemens and Halske, Brush Crompton, Mather and Platt, and Electric Construction Company. The Johannesburg telephone system is said to be the best of its kind in the world, all the most modern improvements having been introduced in connection with it. There is a movement now on foot to connect all the mines on the main reef with the town by a telephonic system. This would be of great economic advantage to the mining companies, though it is doubtful if local mine-store brokers would consider it as such.

SOUTHAMPTON.—A sub-committee of the Works Committee of the Harbour Board recommended at the last meeting that a pair of new armatures required for the electric cranes be ordered from Messrs. Statter and Co. for the sum of £135. The electric light at the Quay extension is now completed, the work having been carried out by the Board's employes under the direction of Mr. G. Taylor, the electrician. The original estimate of the consulting engineer (Mr. Aldridge) was £333, and the total cost has proved to be £244. 3s. 3d. Mr. Aldridge has certified the work as having been done satisfactorily, and the Sub-Committee recommend that a bonus of £10 be paid to Mr. Taylor for the effective carrying out of the work. In moving the adoption of the report, Mr. Bone, after referring to the satisfactory way in which the electric lighting work had been completed, stated that, with regard to their having an electric installation of their own, the Committee were still making inquiries, but did not think it advisable to proceed before they knew what was to be done with regard to the purchase of the local electric lighting company's station by the Southampton Town Council. If the purchase was immediately effected it would doubtless be to the mutual advantage of both bodies that they should take current from the town supply. If the purchase was not effected the Works Committee would be immediately prepared to bring up a report in connection with the putting down of an installation of their own. In the discussion which followed the question was asked as to the working of the electric trams ; this was stated to have been satisfactory, and the report was adopted. On the report of the Finance Committee, Capt. Emanuel objected to the delay of the Board's proceeding with their electric lighting project. They were paying for electric current no less than £530 per annum, which represented a capital outlay of between £13,000 and £14,000, whereas they could obtain a complete installation of their own for £4,000. This question had a distinct bearing upon the question of the purchase of the local company's undertaking by the Town Council. Mr. Bone replied that if the town took over the electric lighting station, a consultation between the Council and the Harbor Board would be advisable, it might probably save the expending a large sum of money, while the members must not overlook the fact that the Board had a contract with the electric light company to pay so much per annum for a number of years.

SNAEFELL (ISLE OF MAN).—Rapid progress is being made with the construction of the electric railway to the top of Snaefell, and it is anticipated that the line will be finished in time for the coming season.

STAFFORD.—The Electric Lighting Committee's report to the last meeting of the Town Council states that the electric supply station buildings are practically complete, the boilers have been satisfactorily tested, and the erection of the engines is now approaching completion.

STRAND (LONDON, W.C.).—From time to time the question of lighting this district by electricity has been under discussion by the Board of Works. Offers for lighting the district have been made by the Charing Cross and Strand Company and the Metropolitan Company, the latter, owing to the terms being more acceptable, meeting with most favour. At the last meeting of the Board a report from the Lighting Committee recommended that no steps be taken to light the district electrically, owing to interference with the streets and foot pavements. After a long discussion, in which the opinion of the members was about equally divided in favour of and against the report, it was ultimately referred back for further consideration. This district is the only important West London district in which the electric light for public lighting is absent, although several of the London companies supply current for private lighting in the district.

TELEGRAPH RATES.—Lord Rosebery received a deputation last week from the Association of Chambers of Commerce in favour of inter-Imperial telegraph rates between this country and the Colonies, and between the Colonies themselves, without such route passing through other countries. Sir A. Rollit, who introduced the deputation, pointed out the dangers our commerce might incur in case of war by the passage through possibly hostile countries of the means of telegraphic communication between the mother country and the Colonies. After remarks from other speakers, Lord Rosebery said he had no decision on the part of the Government to announce. The Government had the matter practically under consideration, and hoped to be able shortly to give a satisfactory reply.

WOLVERHAMPTON.—Complaints are made that the electric lamps used for illuminating the public thoroughfares of this town are extinguished before midnight, leaving the principal thoroughfares practically in darkness. Owing to the brilliance of the lights, the effect of extinguishing the lamps so early is very noticeable. An agitation is forming to secure the lighting of the electric lamps till daylight.

YARMOUTH.—On Thursday next, June 6th, a Local Government Board inquiry is to be held at the Town Hall into the application of the Town Council for powers to borrow £17,590 for electric lighting purposes.

COMPANIES' MEETINGS AND REPORTS.

Reuter's Telegram Company (Limited.)

The thirty-first ordinary general meeting of the shareholders of this Company was held on Wednesday this week, at the offices in Old Jewry, London, E.C., Admiral the Right Hon. Sir J. C. D. Hay, Bart., K.C.B., presiding.

The SECRETARY (Mr. W. F. Bradshaw) read the notice convening the meeting and the report of the Directors.

The CHAIRMAN: Gentlemen, I beg to move the adoption of the report, and congratulate the shareholders on the great improvement it shows over its predecessor. A profit of £4,485, as compared with a debit balance of £2,766 in 1893, means, of course, an improvement of £7,251. It would have afforded the Directors great pleasure to declare a dividend ; but the necessity of dealing with the loss on the operations of 1893 rendered this impossible. When I addressed you last year I mentioned that the fall in silver had prejudicially affected our business, and that we had readjusted our arrangements in the East in consequence. I am glad to say that the measures we then took were attended with the best results. Unfortunately, the economies effected were more than counterbalanced by the heavy expense to which we were put by the war between China and Japan. It is quite true that in our business we must be prepared for wars and rumours of war ; but the reporting of the contest between the two rival Powers in the Far East presented peculiar difficulties, and was attended with large outlays for special correspondents. The war, however, is now at an end, and I can see no reason why we should not be able to resume the payment of a dividend during the autumn, provided we are not again called upon to incur similar exceptional expense. It will afford shareholders satisfaction to learn that the Company gained the lawsuit to which I referred at the last general meeting, and was awarded sufficient damages to cover the legal expenses to which it had been put. I beg to move that the report and accounts now presented be adopted.

The Hon. MARK F. NAPIER, M.P., seconded the motion.

Mr. T. SIMMONS inquired whether the amount of £27,000, due to creditors, was not unusually large.

The CHAIRMAN: I thought that that question might be asked. The apparent disproportion affords proof of the sound way in which the business is conducted, considering that nearly one-third of the liquid assets consists of cash in hand. The main portion of the amount, due to sundry creditors for telegrams and agency charges, is, as a matter of fact,

Digitized by Google

liquidated monthly, and our total assets are approximately 50 per cent. in excess of outside liabilities.

The motion was carried unanimously.

Resolutions were afterwards passed re-electing Baron de Reuter to his seat at the Board, and reappointing the auditors, Messrs. Welton, Jones and Co.

The proceedings terminated with the usual vote of thanks to the Directors and staff.

Consolidated Telephone Construction and Maintenance Company (Limited).

The following report of the Directors of this Company will be presented at the fourteenth annual general meeting of shareholders to be held at Winchester House, Old Broad-street, London, Thursday next, June 6th, at 12 o'clock :—

The operations for the past year show a manufacturing profit of £1,403. 9s. 1d. The amount available for disposal (after the usual provision for doubtful debts, and after writing off £63. 16s. 8d. from the new building account, £12. 19s. 4d. from furniture account, and reserving £57. 8s. 10d. for rentals paid in advance) is £2,866. 10s., from which the Directors propose to pay a dividend of £1. 10s. per cent., leaving a balance of £1,236. 6s. 10d. to carry forward.

The competition (principally foreign) in the manufacturing business has continued with unabated severity, the selling price of all articles having been largely reduced. The lease of the present factory terminates at Christmas next, and it is proposed, if suitable premises can be found, to remove the plant, machinery, &c., to the country, with the object of reducing the expenses of production, in the shape of labour, rent, and the heavy rates now being paid. Various manufacturing proposals have been submitted to the Directors, one of which, for the manufacture of an unique form of battery and accessories, has been adopted, the Company having obtained the sole right to manufacture all supplies required by the patentees of the "Capsule battery" for the whole period of the patent, viz., 14 years.

It is proposed to alter the "Memorandum of Association," to enable the Company to manufacture other articles than those solely electrical, and a resolution will be submitted to that effect at the extraordinary general meeting. The Directors are hopeful that this extension of busines will be advantageous to your Company. A resolution to alter Article No. 83, as to the number of Directors, will also be submitted.

The lawsuit in Belgium, undertaken in conjunction with the Edison Gower-Bell Telephone Company, against infringers of the patent held by the Company, resulted in a successful appeal against the previous decision, and the Court has ordered a claim to be sent in for damages. The Directors have resolved to defer they payment of their fees.

The subsidiary Company, the Anglo-Portuguese Telephone Company, continues to show satisfactory progress, as will be seen by the following comparative statement :—

Year ended March 31st.

Subscribers.		Rental.		Increase.	
1894.	1895.	1894.	1895.	Subscribers.	Rental.
2,320	2,439	£15,076	£16,040	119	£964

Mr. C. L. W. FitzGerald and Mr. J. H. Buckingham retire, and Mr. FitzGerald seeks re-election as Director, and the auditor, Mr. J. G. Griffiths (of Deloitte, Dever, Griffiths and Co.), also offers himself for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

ALLIANCE METER COMPANY (LIMITED).—Agreements which were filed in March and April have been made by this Company with William Coward, of Leadenhall-street, London, E.C., which provide for the acquisition by the Company of the connection of the said William Coward in regard to the purchase and supply of electric and other meters in England and the Colonies, in consideration for the allotment of 2,000 fully-paid shares of £1 each.

EASTBOURNE ELECTRIC LIGHT COMPANY (LIMITED).—The annual return to April 8th has been filed. The nominal capital is £50,000, in £10 shares, of which 1,025 Ordinary and 40 Preference shares have been allotted, and the full amount has been paid.

EDISON GOWER-BELL TELEPHONE COMPANY OF EUROPE (LIMITED). The annual return to April 11th is filed. The nominal capital is £500,000, in £1 shares, of which 385,009 have been taken up ; 370,000 of these have been issued as fully paid, and £1 per share has been paid on the remainder.

ELECTRIC CYCLE SYNDICATE (LIMITED).—The annual return to April 18th has been filed. Out of a nominal capital of £3,000, in £1 shares, 2,827 shares have been taken up, of which 1,000 are considered as fully paid. The full amount has called on the remainder.

ELECTRIC LAMP COMPANY (LIMITED).—The annual return to November 10th last has been filed. The nominal capital is £4,000, in £1 shares, and 2,797 of these have been taken up. 2790 are taken considered as fully paid, and the full amount has been called on the remainder.

ELECTRIC TIME DISTRIBUTING AND CLOCK COMPANY (LIMITED). —The annual return to February 28th has been filed. Out of a capital of £5,000, in £1 shares, 2,084 shares have been taken up, and 2,000 of these have been issued as fully paid ; the full amount has been called on 82 shares, and 10s. per share on the remaining two shares.

MULHOLLAND, MAUGHAN AND CO. (LIMITED).—The annual return to October 24, 1894, was recently filed. The nominal capital of £5,000 is divided into 120 Founders' and 380 Ordinary shares of £10 each. All the Founders' and 177 of the Ordinary have been taken up, and the full amount has been called on the former and £5 on the latter.

NATIONAL ELECTRICAL ENGINEERING COMPANY (LIMITED).—The return, to April 10th, is filed. The nominal capital is £5,000, in £1 shares, and of these 2,614 have been taken up ; 2,000 have been issued as fully paid. The full amount has been paid on the remaining 654 shares.

NEW BRITISH ELECTRICAL INSTALLATION CONTRACTORS (LIMITED). The annual return, to March 4, 1893, was recently filed. The capital is £20,000, in £5 shares, and 100 of these have been subscribed for and allotted, and the full amount called. The annual return to February 10, 1894, is now also filed, and no change is recorded.

NORTH-EASTERN TELEPHONE COMPANY (LIMITED).—The annual return to October 4, 1894, has been filed. The nominal capital is £1,000, in 500 Ordinary and 500 Preference £1 shares ; 425 of the former have been taken up, and 14s. per share paid thereon, while 15 Preference have been taken up and 15s. per share called.

NORWICH ELECTRICITY COMPANY (LIMITED).—The annual return to May 8th has been filed, 2,695 £10 shares have been subscribed for, allotted, and paid out of the capital of £50,000.

ORIENTAL TELEPHONE AND ELECTRIC COMPANY (LIMITED).—The annual return to May 13th is filed. Of a nominal capital of £200,000, in £1 shares, 171,504 have been taken up, of which 171,497 were issued as fully paid to the original shareholders in the Oriental Telephone Company (Limited). £1 per share has been paid on 7 shares.

WYNDHAM ELECTRIC LIGHT COMPANY (LIMITED).—This concern is dead.

CITY NOTES.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend of 3s. per share (being at the rate of 6 per cent. per annum), free of income tax, for the quarter ended March 31st, payable on June 22nd. The transfer books of the Company will be closed from June 15th to June 21st inclusive.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended May 26th were £884, as against £931 in the corresponding period of 1894, being a decrease of £47. The total receipts for the half-year amount to £19,604, against £19,144 for the corresponding period of 1894, an increase of £460.

CROMPTON AND CO. (LIMITED).—A petition for reducing the capital of this Company from £300,000 to £280,000 is down for hearing before Mr. Justice Romer on June 17th. Creditors or shareholders desiring to oppose the making of an order for the reduction of the capital of the Company must appear at the time of hearing. Messrs. Deacon, Gibson and Medcalf, 9, Great St. Helens, E.C., are solicitors for Messrs. Crompton and Co. (Limited) in this matter.

THE ELECTRIC CONSTRUCTION COMPANY (LIMITED).—The Electric and General Investment Company notify that a drawing of Six per Cent. Second Mortgage Debentures in the Electric Construction Company (Limited) will take place at 1 and 2, Great Winchester-street, London, E.C., on June 7th next.

HASTINGS AND ST. LEONARD'S-ON-SEA ELECTRIC LIGHT COMPANY (LIMITED).—The annual meeting of this Company was held at Hastings on the 23rd inst., Mr. F. A. Langham presidin . The Chairman moved the adoption of the report, and said he regretted they were not in a position to pay a dividend. They were doing more work ; but, on the other hand, the expenses also had very largely increased. They had plenty of customers, and should have a great many more if they were in a position to supply more, and to carry their mains further in the town. They were crippled for want of capital. There were many people willing to take the light, but they would not supply it because of the expense of laying it on. The Directors found that the installation work was not a prosperous branch of the Company, and had determined to confine the business of the Company to supplying current. After some criticism, the report was adopted. Mr. G. Roddis was re-elected a Director, and a vacancy on the Board was filled by the election of Mr. A. L. Ward.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 26th inst. amounted to £1,135. The amount for corresponding week last year was £874.

RUSTON, PROCTOR AND CO. (LIMITED).—The annual report of the Directors of this Company to March 31st last states that, with the balance forward of £3,281, a profit balance is shown of £49,737, from which it is proposed to pay a dividend of 10s. per share, free of income tax, equal, with the interim dividend paid on November 1st last, to 7½ per cent. for the year. £8,000 is written off goodwill account, and £3,438 off the costs and charges incidental to the conversion of the Five per Cent. Debentures, leaving a balance forward of £3,065.

SNOWDON MOUNTAIN TRAMROAD AND HOTELS COMPANY (LIMITED) —During the week the Directors of this Company, which has been formed for the purpose of constructing a tramroad (to be worked by electricity) from Llanberis to the summit of Snowdon, have invited applications for 6,343 shares of £10 each, and £20,000 Four and a-Half per Cent. First Mortgage Debentures of £100 each.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended May 24th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,712.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 890. [No. 6. Vol. XXXV.] FRIDAY, JUNE 7, 1895. PRICE SIXPENCE.

NOTES.

The Board of Trade draft of the new Regulations and Conditions for the Safety of the Public, in the matter of electric supply, which we reprinted and commented upon in our issue last week, will have the effect, if put into force, of considerably modifying at least one branch of electric lighting —to wit, the use of small arc lamps for lighting shop and other exteriors. No one can have failed to notice the rapid and extensive increase of this class of apparatus, and anyone who has compared the relative economy and convenience of small arcs and large incandescent lamps for shop exteriors will probably have discovered the superior merits of the former. But, as has been pointed out to us by an arc lamp expert, all this seems likely to be quashed, and the use of arc lamps in this way "in any street" will become difficult if the 10ft.-from-the-ground rule is to be enforced. It is easy to see why large arc lamps, with bulky globes protected only by wire netting, should be placed beyond the possible thrust of a giant's umbrella; but it is not so easy to comprehend why it is that small arcs placed in suitable metal reflecting cases in front of shop windows should be treated more stringently than gas or oil lamps similarly situated.

Nor is this the only blow which the new proposed regulations may possibly direct against arc lighting. In Section VII., paragraph 47, it is provided that these lamps "shall not be used in situations where there is any danger of the presence of explosive dust or gas." The expert above referred to a man of unsurpassed experience in arc light matters, is inclined to regard this regulation as being too stringent, because this danger exists in every building where gas is used. We hardly think, however, that it can be the intention of the Board of Trade to prohibit the use of arcs and gas jets in one and the same building. As well lay down a law that no building shall have two or more gas jets, on the ground that one might be "escaping" while the others were alight.

If the effects and probable causes of lightning discharges were on every opportunity investigated with painstaking accuracy and recorded concisely and clearly, we should very soon be in a position to attach a correct value to the warning always brought forward by "practicians" as to the danger of arguing from Wimshurst machine sparks to actual atmospheric discharges. In his account of the damage done by lightning to some telegraph and telephone cables in the St. Gothard tunnel last autumn, Dr. Preller shows tolerably conclusively that the "side flash" phenomenon is no figment of the experimenter's imagination, and that a good earth and plenty of plain plate protectors and fuses afford but little security unless considerable inductance is added to the circuit, as suggested by Dr. Lodge and carried out in his well-known lightning arrester. The results of the experiments of Zielinski, quoted by Dr. Preller, although labouring under the normal disadvantage of relating to imitation thunderstorms, are nevertheless interesting as giving in a rough quantitative form the efficiency of impedance coils having various amounts of self-induction when applied to the protection of circuits of various resistances. It will be seen that, with resistance values such as are generally met with in practice, a very small impedance coil effectually shunts the discharge to earth. The manner in which the proportion of the discharge going to earth decreases as the resistance of the circuit increases should convince those who not unnaturally are impervious to mathematics that the effect is an inductive one; although the simultaneous publication of the results of a similar set of experiments on the same circuit, without the impedance coils, would in all probability have been even more convincing to those who still held the faith of the path of *least resistance*.

An engineering teaching institution, where the enrolment of students in the electrical engineering department alone is over two hundred, can well afford to do things on a more liberal and magnificent scale than even the best of English institutions of a similar kind. Some years ago an English professor of engineering amused his audience by boasting that "within the last year his civil engineering students had increased four hundred per cent."—*i.e.*, from one individual to five! In another column will be found a brief description of Purdue University, the engineering school of the State of Illinois, U.S.A., which rejoices in the above-stated abundance of electrical students.

At this institution there are five departments, each one located in a separate building, and each provided with a set of well-equipped laboratories and lecture rooms. Apart from the sumptuousness of the material arrangements, things appear to be very similar to those in our English technical institutions. The freshman goes through one year's training in physics, mathematics, &c., on lines which are practically

Digitized by Google

independent of the particular branch of engineering to which he intends to devote himself subsequently. In the second year, the embryo electrical engineer turns his attention to purely mechanical engineering in the mechanical laboratory, and to the lighter branches of electrical science; and in the subsequent stages his mechanical laboratory work is directed more particularly to its electrical applications, and the studies are more highly specialised. As in this country, considerable value is attached to visits to actual engineering works, and the student, in his later stages, is required to write a thesis on some line of experimental work undertaken by him.

PERHAPS the most interesting point in connection with the researches of Prof. MINCHIN on "The Electrical Measurement of Starlight," an abstract of the Royal Society Paper describing which will be found in our columns this week, is the surprising agreement between the photo-electric and the photometric determinations of the magnitude of a given star. Thus, for example, the photometric estimate of the magnitude of Regulus is usually taken to be between 1·42 and 1·70, while Prof. MINCHIN's photo-electric estimate is 1·43. It is difficult to see that there is any real physical identity, or even connection between the two magnitudes, for, as a matter of fact, it is not so much star *light* as star radiation, between the limits of certain wave lengths, upon which the photo-electric measurement is based. While, of course, the photometric measurement is purely optical, the photo-electric method measures radiant energy in the infra-red and ultra-violet parts of the spectrum. It will be interesting to see whether, in the extended researches which Prof. MINCHIN is about to undertake, this close agreement will be found to hold for the majority or even a considerable number of stars. In the present stage we can only surmise that Regulus and the comparison star happened to be at about the same temperature. But the great range of temperatures in the generality of stars would lead one to expect that, as a general rule, the photometric comparisons of star magnitudes would give results appreciably different from the photo-electric ones.

THOSE who were interested by Prof. J. J. THOMSON'S researches on the effect of moisture, more especially aqueous moisture, on the conditions of electrical discharge in high vacua, which were so prettily and convincingly demonstrated at the meeting of the British Association at Oxford last autumn, may read with further interest the reprint of his lecture on "Electric Discharge through Gases" in our issue this week. The experiments and inferences detailed in this lecture are, in fact, preliminary to the important conclusions relative to the influence of aqueous moisture; and there is a further interest arising from the similarity of the apparatus and methods adopted in the two cases. Both chemistry and physics owe much to such lines of research as these; and it is more than probable that developments of both branches of science will be effected by similar investigations of physico-chemical action. It is, indeed, in the direction of the behaviour of gases under electrical stress and discharge that physicists and chemists are principally looking for the solution of the problems of ether and atomic phenomena. Though comparatively useless in technical and commercial work, as yet, the vacuum tube has rendered inestimable service to pure science.

IN a recent number of the *Comptes Rendus* the construction of a very sensitive galvanometer is described by M. PIERRE WEISS. Among the points of interest occuring in the Paper two are of special importance. In the first place, the magnetic system consists of two magnets arranged vertically instead of, as is usual in galvanometers, horizontally. By arranging these magnets with dissimilar poles uppermost a perfectly astatic combination is formed, which is not subject to any demagnetising tendency and consequent alteration with time. Such an arrangement is not new, for it has been adopted in some English instruments; but its advantages are as yet very little known to makers of galvanometers. In order to get the fullest sensibility out of this combination, the magnets should be close together, and the moment of inertia of the suspended system should be reduced to a minimum. In order to accomplish this, M. WEISS, in one of his galvanometers has adopted dimensions which remind us somewhat of the instruments made by Prof. BOYS. The needles are attached to the edges of a strip of mica 1·2mm. wide. They are 18mm. long and 0·2mm. in diameter. The mirror is attached to the bottom of the strip, and weighs only eight milligrammes, measuring 7mm. by 2mm. If this system is delicately suspended, and the controlling magnet adjusted till the movements of the needle are nearly "aperiodic," the measurements given by M. WEISS seem to show that this instrument is as sensitive as any which has yet been constructed. It is, however, almost impossible to compare galvanometers when each is adjusted to give its utmost deflection for a given deflecting force. So much depends on the stability of the zero, a quantity which is not easy to specify. It is theoretically possible to make any galvanometer infinitely sensitive by sufficiently diminishing the controlling field, but if this is attempted it is soon found that the indications of the instrument are unreliable and worthless. Galvanometers, if compared at all, must be compared under conditions in which they are well under control. M. WEISS's Paper clearly shows that the instrument constructed is extremely sensitive, but the author gives no information regarding the reliability of the deflections when the utmost sensitiveness was obtained.

Royal Society Soirée.—The annual conversazione of the Royal Society will be held on Wednesday, June 12th.

Cable Interruptions:

	Date of Interruption.
Chorillos—Iquique	June 4th, 1895.
Mollendo—Arica	June 4th, 1895.

Institution of Civil Engineers.—During the past session of this Institution a Crampton Prize has been awarded to Mr. John Richardson (of Lincoln), for his Paper on "The Mechanical and Electrical Regulation of Steam Engines."

Electric Mountain Railways.—The cars ascending Mont Cervin and the Gauergrat, to heights exceeding 10,000ft. above the sea, are to be propelled by electricity, the power being derived from a neighbouring waterfall.—A concession has been granted for an electric rack railway between Heiligenblut and Glocknerhause.

Digitized by Google

International Telephonic Communication.—Negotiations are, it is stated, in hand between the Hungarian Government and the Servian Minister of Commerce, with reference to the establishment of telephonic communication between Budapest and Belgrade.

Non-Conducting Coverings for Steam Pipes.—Steam pipes are now being covered with a fabric made of large reeds laced together into mats. A layer of fossil meal is laid both below and over the reeds. The covering is being applied by Messrs. R. M. Moir and Co., of St. Swithin's-lane.

Obituary.—*The Times* Paris correspondent announces the death, at the age of 55, of Rear-Admiral Fleuriais. He was a distinguished scientist, and commanded one of the expeditions for observing the transit of Venus, and invented and improved an electric log. (See *The Electrician*, Vol. XXXIV., p. 392.)

Society of Engineers.—The Council of this Society announce that they have succeeded in making arrangements with the Council of the Royal United Service Institution for holding the future ordinary meetings of the Society in the Lecture Theatre of the Royal United Service Institution, Whitehall.

Static Electricity in American Paper Mills.—In certain paper mills in North Hoosick, N.Y., static electricity is giving trouble. In some cases sparks 6in. to 8in. in length are produced as the paper leaves the calender. A steam damper is used to prevent this, or a copper wire, well grounded, is made to rest on the web as it passes from the calenders to the reels.

Electric Light for the Kremlin.—The electric light is about to be put in at the Kremlin. The lighting will comprise 15,000 4 c.p. "candle-stick" lamps, 2,000 16-c.p. lamps and 40 arc lamps. The whole contract has been placed with Messrs Schuckert and Co., of Nuremberg, and has to be completed by the beginning of next year in time for the coronation festivals.

Alternating Current Patent Litigation in Germany.—The Helios Company of Cologne has sued the Corporation of Chemnitz and Messrs. Siemens and Halske, of Berlin, for infringing patents owned by them. The Helios Company demand the removal of all the infringing apparatus, and claim £2,000 damages. The Town Council has decided to let the matter go to the law court.

The Electrical Industry in London.—According to Mr. Charles Booth, in his latest volume of "Life and Labour of the People in London," the great majority of men employed in all the branches of electrical work in London are under 25 years of age. In another way the statistics of the electrical trades are highly interesting, for from them we learn that of some 5,000 men engaged in different electric works only 13 per cent. are members of a trade union.

Maschinenfabrik Oerlikon.—This firm delivered last month its 3,000th dynamo. The total number manufactured up to date is 3,318. Unfortunately, the aggregate output of this grand total is not stated. The total number of transformers manufactured is 1,843. More than one-half of these totals has been made up during the last two years. In the same time 69 electric travellers of a total capacity of about 755 tons were manufactured.

The Electric Lighting of the Chambre des Députés.—The contract for the lighting of the Chambre des Députés has, says *La Sémaine Electrique*, been given to M. Ch. Mildé, of the Société des Anciens Etablissements de Cail. Cail engines and Helmer dynamos will be used, the boilers being supplied by a Glasgow firm. The firm of Bréguet some time ago offered to put in an installation for £20,000, and to run it for £2,880 a year; but the work was finally put up to public tender.

Damage by Lightning.—During a severe thunderstorm on Thursday afternoon last week six labourers took shelter by a wheat stack at Pirton, near Hitchin. The stack was struck by lightning, one man being killed on the spot, another so badly injured that his recovery is doubtful, and three others were slightly hurt. The lightning also struck a house in the village of Pirton, and it and three adjoining houses were burnt down. At Southport, about half-past six o'clock, a house was struck by lightning, which travelled down the wall of one of the bedrooms, fusing a gaspipe, and setting the gas ablaze.

Leakage from Gas Mains.—Notwithstanding the reiterated asseverations of the gas journals that, as it was to the obvious interest of the gas companies to prevent leakage from their mains, it might reasonably be supposed that in this matter all was for the best in this best of all possible gas worlds, the recent outburst of repairing energy in the City which, judging by the olfactory sense, is none too soon, may be surmised to have some connection with the attention which has recently been drawn to the delinquencies of the gas companies by electric conduit explosions. Thus once more has electricity, out of the fulness of its heart, done a good turn to its rival.

The New Board of Trade Regulations.—The following "whip" has been sent round by the Chairman of the Electrical Trades' Section:—

Urgent and Important.—Revised Board of Trade Regulations under Electric Lighting Acts, 1882 and 1888.

Dear Sir: You will doubtless have seen a copy of the revised "Regulations and Conditions for ensuring a Proper and Sufficient Supply of Electrical Energy made by the Board of Trade under the Provisions of the Electric Lighting Acts, 1882 and 1888." The Electrical Trade Section of this Chamber have had these regulations under their consideration, and think it desirable that the views of central station engineers and others interested should be obtained before representations are made to the Board of Trade on the subject. We shall, therefore, esteem it a favour if you will kindly give these regulations your consideration, and send the Secretary of the Chamber at your earliest convenience any suggestions you may have to offer. A meeting of the Section will be held on Tuesday, June 11th, at 12 noon, to consider the regulations and any suggestions made, and to determine the nature of the representations to the Board of Trade.

Cathode Rays.—At a recent meeting of the Société Française de Physique, M. Curie described some experiments he had made to see whether light rays were deviated by a magnetic field in the same manner as cathode rays. He has obtained no deviation, although his apparatus permitted him to pass the light rays for a distance of 20cm. in a strong field, the direction of propagation of the light being perpendicular to the lines of force. The experiment was made in air, as well as in carbon bisulphide in which sulphur has been dissolved. The author, although he does not think the above experiments are conclusive proof that cathode rays are radiation of a different nature from that which constitutes light, yet thinks they tend to show that there is some difference. Furthermore, if the cathode rays are analogous to light rays, it is difficult to explain the absence of double refraction when a magnetic field acts on the cathode rays.

Magnetisation of Iron in very Weak Fields.—An interesting Paper on the "Magnetisation of Iron in very Weak Fields," by W. Schmidt, appeared in a recent number of *Wiedemann's Annalen*. The curves obtained for iron and steel show that for fields up to 0·06 C.G.S. unit the susceptibility is constant, thus confirming Lord Rayleigh's results. The author sums up the results of his experiments as follows:—Steel follows weak magnetising forces more quickly than iron. The susceptibility of soft steel is for small magnetising forces greater than that of iron. Thus for fields less than 0·06 C.G.S. unit the susceptibility of soft steel is to that of iron in the ratio of 4 to 3. For magnetising fields of about 1 unit the susceptibility of the two is about the same, while for greater field strengths the susceptibility of iron is greater than that of steel. The limits within which the susceptibility remains constant vary considerably for different samples, but the author considers that 0·06 C.G.S. unit may be taken as the upper limit with sufficient accuracy for most purposes.

Power Transmission Plant at Sacramento.—According to the American technical journals a plant of some interest is now in course of erection between Folsom and Sacramento, a distance of 30 miles. The power plant, which is located on the bank of the American river, consists of four pairs of wheels of the McCormick horizontal-shaft turbine type, enclosed in steel cases, having steel inlet pipes 8ft. in diameter, and double discharge tubes. By this arrangement in pairs the end thrust is neutralised. The governors used will be of the Faesch-Picard type, and will be supplemented with heavy flywheels on the water-wheel shaft. Each pair of wheels will have a capacity

Digitized by Google

of 1,260 H.P., at 300 revolutions per minute, and will operate when under a head of 55ft. The hydraulic plant also includes two horizontal wheels for the exciters. The four generators will be of the three-phase alternating current type, generating current at 800 volts potential, and will be directly connected to the shafts of the wheels. Each generator will have a capacity of 1,000 H.P., and will weigh about 30 tons. Step-up transformers will transform the current generated to 11,000 volts. The conductors will be carried on two pole lines to the Sacramento transformer station, two lines being erected to prevent a shut down should one line get out of order.

Electric Snow.—An American story of a sufficiently remarkable snowstorm is attributed by *Electricity*, of New York, to Lieut. John P. Finley, one of the best-informed meteorologists in the United States, who, it is said, encountered the storm in making an ascent of Pike's Peak. He says the storm could best be described as a "shower of cold fire." In reality it was so charged with electricity as to present a scene more easily imagined than described. At first the flakes only discharged their tiny lights on coming in contact with the hair of the mule on which the lieutenant was mounted. Presently they began coming thicker and faster, each flake emitting its spark as it sank into drifts of the snow or settled on the clothing of the lieutenant or the hair of the mule. As the storm increased in fury and the flakes became smaller each of the icy particles appeared as a trailing blaze of ghostly white light, and the noise produced by the constant electric explosions conveyed an impression of nature's power which Lieut. Finley will never forget. When the storm was at its height "each flake of snow was like a drop of fire, electric sparks were shaken in streams from the lieutenant's finger tips, as well as from his ears, beard and nose, and a wave of his arms was like the sweep of flaming sword blades through the air, every point of snow touched giving out its little snap and flash of light."

The Use and Abuse of Examinations.—In the Mental Science and Education section, of the Australasian Association for the Advancement of Science, during its meeting this year at Brisbane, Dr. Henry Belcher contributed a Paper on "The Use and Abuse of Examinations." The advantages of the examination system were shortly stated as follows:—"It enables the teacher to stimulate the intelligence and test the progress of the pupil, and to fill up flaws and gaps due to imperfect apprehension, carelessness, or defective memory; it is a power almost indispensable to the teacher's efficiency, and is thus a potent factor in general education; it had an alterative and prophylactic effect upon private adventure schools, raising their tone both intellectually and morally. The author doubted whether it was wise to entrust the examination of pupils to persons other than their teachers. The disadvantages of the examination system were that the best part of a teacher's work escapes analysis; methods of higher teaching rise in quality and character, while methods of examination lie behind; by the selection of set books, and the publication of manuals thereon, an intolerable yoke and shackle is placed upon elementary scholarship; examinations appeal to the lower side of human nature—what will pay becomes the pupil's ruling thought. Certain subjects of great importance are neglected because they do not largely count for prizes and honours; and research is altogether neglected."

The Resistance of Diaphragms.—In a short note in the *Zeitschrift für Elektrochemie*, of June 5th, Dr. Fritz Krüger refers to some experiments on the resistance of diaphragms which are now being carried out in the electrochemical laboratory of the Berlin Technische Hochschule. Although, says Dr. Krüger, it is incorrect to speak of the resistance of diaphragms (porous-clay or porcelain), as these are non-conductors of electricity, the custom has become general, and one simply means by it the resistance which the electrolyte receives as it passes through the porous partition. In investigating the behaviour of porcelain and clay in different electrolytes, Dr. Krüger measured the diaphragm resistance by means of a Kohlrausch bridge and telephone. As electrodes he used platinum plates, the connecting wires of which were conducted through a double-bent glass tube in which they were fixed by means of a cork and sealing wax. The distance between the electrodes was the same in all experiments. Before commencing the test, Dr. Krüger soaked the diaphragms thoroughly in the electrolyte. First, the resistance of the electrolyte was ascertained, and then the diaphragm was inserted between the electrodes and the total resistance was measured. The difference between the two was taken as the required resistance. The results merely show that the resistance of the diaphragm increases with the resistance of the electrolyte, and is most likely proportional to the specific resistance of the latter. This method should, Dr. Krüger thinks, be suitable for ascertaining the value of various diaphragms for various electrolytic purposes, since, after the determination of the resistance of a diaphragm in one electrolyte with a known conductivity, the resistance for all other liquids with known conductivities can be calculated.

Electric Coal Haulage and Hoisting Wharf Plant.—The *Engineering and Mining Journal* describes, in a recent number, an extensive coal-handling plant, operated entirely by electricity, which has been running in San Francisco for the past few months with marked success. The plant consists of an electric hoisting and haulage system for unloading the coal-carrying ships and steamers, and distributing the coal into wharf and house bunkers for local and wholesale distribution. The plant consists of three 100-H.P. boilers and two 11 × 18 × 14 tandem compound high-speed 135-H.P. engines, running at 265 revolutions. Belted to these engines are two K.W. 250-volt compound-wound multipolar dynamos, running at 700 revolutions, and over-compounded 10 per cent. The load on the dynamo is very variable, often changing from no load to 75 per cent. of full load in from 5sec. to 10sec., and from full load to no load in about the same time. The hoisting plant consists of three special electric hoists, each having a capacity of 2,000lb. lifted at a maximum rope speed of 800ft. per minute. The motor is geared to an intermediate shaft by special gears with a very slight reduction in speed. The intermediate shaft is in turn geared to the drum shaft by means of eight groove V friction pulleys. On the end of the intermediate shaft is also a single-groove wheel driving the hauling-in drum which serves to haul in the bucket over the shoots when it has been raised to the proper height. The buckets have a capacity of 1,200lb. of coal each, and are raised from a depth of 60ft. to 80ft. The derricks are mounted on a track raised about 6ft. above the floor of the bunkers, and are so arranged that they can be moved along the wharf to accommodate themselves to the position of the hatches of ships. The capacity of each derrick is 400 tons in nine hours, although they have, under favourable conditions, worked up to 450 tons in nine hours. Two electric locomotives are used, with trains of four cars, to distribute the coal among the coal sheds. The locomotive has a draw-bar pull of 800lb., and is required to haul from four to six loaded cars, each car weighing 3,600lb., and having a capacity of 4,700lb. of coal. The train represents a gross load of 40,670lb.

Electromotive Force from Thermo-Chemical Data.—In the *Berichte der Deutschen Elektrochemischen Gesellschaft* appears a Paper by Le Blanc, in which he discusses and objects to the common method of deducing the E.M.F. of a cell or the E.M.F. required for electrolysis from known thermo-chemical data. This method is due to Thomson, and assumes that the chemical energy which disappears in a cell reappears entirely in the form of electrical energy. Knowing the heats of formation and solution of the various substances which can take part in an electro-chemical reaction, we can calculate the resulting E.M.F. Conversely, it is assumed that in any electrolytic process the electrical energy which disappears in the electrolytic cell reappears entirely in the form of energy of chemical separation. For example, let E denote the minimum E.M.F. required for the electrolysis; now, suppose a current, C, to flow for a time, t, then the work done by the electric current is $C t \times E$, and this expressed in heat units is $J C t E$, where J is Joule's equivalent. If H denotes the thermal values of the electro-chemical reactions produced, then $H = J C t E$, from which E can be calculated when the necessary heats of formation, decomposition, &c., are known. Now, the cases to which Thomson's rule was

Digitized by Google

first applied gave quite satisfactory results. The theoretical calculation gave 1·08 volt as the E.M.F. of a Daniell cell, and 1·7 volt as the minimum E.M.F. required for the electrolysis of water under ordinary conditions. An experiment confirmed these results. But cases were gradually discovered in which the agreement between theory and experiment were not so satisfactory, and in which the observed E.M.F. was sometimes less and sometimes greater than that deduced by calculation. The rule, in fact, according to Le Blanc, only holds good for cells of which the E.M.F. is quite independent of temperature. The Daniell cell happens to be one of these; but there are comparatively few of them. The equation given above can be modified so as to take into account the change of temperature. Let dE/dT be the temperature coefficient of the cell, *i.e.*, the rate at which the E.M.F. varies with temperature. Then, as Helmholtz puts it, the equation given above becomes $H = J C t E - J C t T (dE)/(dT)$. This equation, again, assumes that the pressure remains constant; for example, it is known that a smaller E.M.F. than 1·7 volt will suffice for the electrolysis of water when the atmospheric pressure falls below the normal pressure. But as most electrolytic work is carried out under practically atmospheric pressure, the small variations of E.M.F. due to changes of pressure are not of any practical importance.

Rate of Loss of Charge in Bad Conductors.—A recent number of *Comptes Rendus* contains an interesting Paper by M. Branly on the rate of loss of an electric charge due to the effect of light in the case of badly conducting bodies. When the source of illumination is a body heated to a dull red, it is the chief condition of the illuminating surface which plays the chief part in the phenomenon. The nature of the charged body seems to have no effect. In the case where the illumination is rich in highly-refrangible rays, however, the case is quite different, and the chief results obtained are as follows:—A disc of wood or marble, polished or unpolished, shows a marked loss of electricity when illuminated. If the disc is negatively electrified, the loss is more rapid than if it is positively electrified; but the difference is very much less marked than is the case with metal discs, particularly if they are polished. Similar results are obtained with cardboard, terra-cotta, and glass heated to 100deg. The loss of a positive charge is rapid, while that of a negative one is slow in the case of varnished wood, or wood coated with a thin layer of oil, paraffin or tallow. With a metal disc coated with tallow, the loss when negatively electrified is slow, while the loss when positively electrified is very rapid. If a disc of polished wood, in which the loss of a negative charge is more rapid than that of a positive one, though the difference is not very marked, has the surface covered with a thin coating of plumbago, the loss with a negative charge becomes much more rapid than with a positive one. A metal plate covered with grease only loses a negative charge very slowly, the rate of loss of a positive charge being rapid. If, however, a thin coating of copper filings is spread over the tallow by means of a sieve, the loss with a positive charge becomes much more rapid than with a negative one. If powdered aluminium is used in the place of copper, the rates of loss in the case of positive and negative charges becomes nearly equal.

Electric Motors for Machine Driving.—The plan of having each separate machine in a shop driven by a separate motor, says *Engineering*, is of ancient date, as, if we remember rightly, small atmospheric motors were thus used in the works of Boulton and Watt, nearly a century ago. It is easy to show that with fairly efficient motors the amount of power required is considerably reduced, particularly as the shafting in an engineer's shop is usually badly maintained, forming a good instance of the old adage that the shoemaker's children go worst shod. On the other hand, the total amount of power used in a machine motor is usually exceedingly small, as a 50-H.P. engine will drive quite a large tool shop easily, and hence the total saving to be effected is often insignificant and quite insufficient to offset the extra cost of the motor, save under special conditions. It must, however, be confessed that the maintenance of the various driving belts is by no means insignificant, and often the breakage of a main driving belt may stop the whole of the machines for an hour or more. Nevertheless, the plan of independent driving has, up to the present, advanced but little, though the advent of the electric motor has caused a revival of the subject. At the gun factory at Herstal, Belgium, the system is being tried on quite a large scale, though the independent driving does not extend to each separate machine, but only to the main lines of shafting, which, though in different buildings, are all driven by one central engine by means of electric transmission. The plant comprises two 37 H.P. motors, nine 16-H.P. motors, and five others ranging from 3 H.P. to 21-H.P. The working of the plant has been very satisfactory, and overloads are, it is stated, quite as permissible as with belt driving, one 16-H.P. motor being run for several days at an output of 30 H.P. The system is, of course, much less cumbersome than belt driving, as in the latter case straight leads for the belts are required, whilst the electric mains can be run anywhere. In certain other instances, also, the electric system has great advantages, especially in cases in which it is impossible to bring the work to the machine, and so becomes necessary to take the machine to the work. The deck planer used by Messrs. Denny Brothers is a case in point, and the special tools for cutting out tubes and drilling holes, &c., in use at the Crewe Works, is another. The lead taken here has, we note, been followed in the United States, where Messrs. Cramp have adopted the planing machine mentioned above, and several other firms have copied Mr. Webb in the adoption of special portable tools electrically driven, which were described and illustrated in *The Electrician* of May 3rd, page 7.

The Waterloo and City Railway.—The contract for this railway was taken by Messrs. Mowlem on June 1st last year, and on the 18th of the same month the first pile of the river staging was driven. When the stage was completed, two cast-iron cylinders were let down from its centre, one over each tunnel of the two lines. Each cylinder was 16ft. internal diameter. The rings of the cylinder were 9ft. in length, the total being 45ft. from top to the cutting edge. The cylinders were brought down into the clay by union screw tackle. They were then underpinned by brickwork. The next operation was to construct the shields, and get them into position. When this was done, the shields were jacked forward in each direction, the work having been commenced in the middle of the two lines. The tunnelling had proceeded satisfactorily, but on November 26th the up tunnel had reached a point Citywards across the river through the clay, until the heading was under the Thames Embankment by De Keyser's Hotel, when the Metropolitan District Railway objected to further advance without the use of compressed air, although the clay still afforded from 6ft. to 10ft. of cover at that point. The down tunnel was commenced on January 16th in the present year, and was driven forward until, on April 26th, it had come within 20ft. of the former tunnel. It was not until May 22nd that the plant was ready for compliance with the requirements of the District Railway. In the direction of Waterloo the up tunnel was started on December 10th, but was stopped in February when under some property on the Surrey side. Owing to litigation, work on this tunnel was stopped until March 14th. Subsequently the work has been resumed, and the heading is now under Stamford-street. The down tunnel was commenced on January 28th, and was continuously pushed forward until water-bearing strata were encountered on the 4th of last month. A bulkhead and air-lock was at once put on. At the same time, an air-lock was built in a bulkhead in the up City tunnel, and a bulkhead only in the down City tunnel, the latter without any lock on. Mr. Galbraith, the Company's engineer, had suggested the simple expedient of constructing a cross passage between the two tunnels, and working the materials from both faces through the one lock. This has been of the greatest benefit, not only to the contractors but to the Company, as it has facilitated the resumption of the work at an earlier date than could otherwise have been practicable. All these impediments have been surmounted, and lengths of 50ft. of completed tunnel are being accomplished at every face per week. Each tunnel is thus advancing 100ft. from week to week completed, under the charge of Mr. Dalrymple Hay, the resident engineer.

ELECTROMAGNETIC THEORY.—LXIX.*

BY OLIVER HEAVISIDE.

(Continued from page 43.)

§ **267.** A more comprehensive case than the last, bringing a fresh peculiarity into view, is that of the effect due to an initial charge at a single place when the cable is earthed at both ends. There are two solutions in terms of waves, one for the region to the left, and the other for that to the right side of the source. To find them put $a = -1 = \beta$ in (65), (66), § 263, and also $h = pQ$, as there described. Then we obtain

$$V_1 = \frac{\text{shin}\, qy}{\text{shin}\, ql}\, ql\, \text{shin}\, q(l-x)\, \frac{Q}{Sl}, \tag{18}$$

on the right side of the source, which is a charge Q initially at the place $x = y$. To obtain V_2, the potential on the left side, interchange y and x in the last equation.

We see that we have the same denominator shin ql as before. This is clearly because the terminal conditions, earth on at both ends, are unchanged. The denominator sums up the reflective action of the ends. But it is not to be supposed that changing the terminal conditions necessarily changes the determinantal equation. For that depends upon both terminal conditions, and a change in one may be balanced by a change in the other. Thus, if both ends were cut, the denominator would be unaltered, since the signs of both a and β would be reversed. It is their product that determines the subsidence rates, as we see by (65), (66), § 263, which show that, in the general case,

$$\epsilon^{2ql} = a\beta \tag{19}$$

is the determinantal equation.

Returning to (18), and using the result (4), we get

$$V_1 = \text{shin}\, qy\, \text{shin}\, q(l-x)\, \frac{Q}{Sl}\,(1 - 2\epsilon^{p_1 t} + 2\epsilon^{p_2 t} - \ldots), \tag{20}$$

with the same values of p as before. The final steady V is zero obviously, so there is no outside turn, and we get at once by putting $q^2 = -s^2$,

$$V = \frac{2Q}{Sl}\,\Sigma \pm \sin sy\, \sin s(l-x)\, \epsilon^{pt}; \tag{21}$$

or, since $\sin sl = 0$,

$$V = \frac{2Q}{Sl}\,\Sigma \sin sy\, \sin sx\, \epsilon^{pt}. \tag{22}$$

We have in the last two equations written V for V_1, because the interchange of x and y makes no difference. That is, (22) represents V at x due to Q initially at y, whether x be to the right or left of the source. Only one Fourier series is required to represent the essentially different results to the right and left of the source.

Putting $t = 0$ and dismissing constant factors, we see that if

$$u = \frac{2}{l}\Sigma_1^\infty \sin\frac{n\pi x}{l}\sin\frac{n\pi y}{l}, \tag{23}$$

the summation including all integral values of n from 1 to ∞, then u represents 0 everywhere between A and B, except at the point $y = x$, where it is infinite. But its space total is 1, because the space total of SV in (22) is Q at the first moment, before any of the charge has left the cable.

The function u therefore expresses an impulsive function, like the $p1$ with which we were concerned before, only now the variable is x instead of t, or the function is distributed in length instead of time. Such functions can be represented in various ways. Every Fourier series involves one form.

If we multiply a continuous function of y, say $f(y)$, by u, an impulsive function which exists only at the point $y = x$, the product is obviously zero except at that point, where it is infinite. But if we take the space total of the product $uf(y)$, the result is $f(x)$. For u only exists at x, and its total is 1. Thus,

$$\int uf(y)dy = f(x), \tag{24}$$

if the limits include the point x. If not, the result is zero. This is the property made use of in Fourier and other series when employed to express arbitrary functions. The function u, in the above or other special form, spots a single value of the arbitrary function in virtue of its impulsiveness.

Suppose, however, that the given function $f(y)$ had no definite value at a particular place, as happens when there is a discontinuity, or sudden jump from one value to another. Here $f(y)$ has any value between the two extremes. Under these circumstances, what should we expect the impulse to do, if it can only, through (24), lead to one value? To be quite fair, it should show the mean value. This is an excellent reason why it ought to do so, though not a proof that it does. Why it must may become clear later on.

Applying (24) to the problem in hand, with u as in (23), we see that

$$f(x) = \frac{2}{l}\Sigma_1^\infty \sin\frac{n\pi x}{l}\int_0^l f(y)\sin\frac{n\pi y}{l}dy \tag{25}$$

expands the arbitrary function $f(x)$ in a series of sines, so as to vanish at $x = 0$ and l (where, of course, if $f(x)$ does not vanish, the formula fails). We also see that

$$V = \frac{2}{l}\Sigma_1^\infty \sin\frac{n\pi x}{l}\,\epsilon^{pt}\int_0^l V_0 \sin\frac{n\pi y}{l}\,dy \tag{26}$$

represents the potential at x at time t after the moment when the potential was represented by V_0. The former Q is represented now by $SV_0 dy$, that is, the charge on the element of length dy.

The formula (25) may, as we have seen, fail either at the terminals or intermediately at a discontinuity. But the formula (26) does not fail at all, for any finite value of the time. Initially it is the same as (25) and may fail then. But the presence of the time functions makes V continuous. No matter how small t is taken, if not actually zero, there is no discontinuity. Sharp corners in V_0 are instantly rounded off by the time factors, though if graphically represented there might be no observable difference. We may take t so small that the time functions differed from 1 insensibly for millions of terms, yet go far enough, and we must come to time-functions differing insensibly from 0 with the same value of t. So V is necessarily made continuous in the smallest interval of time after the first moment, if it be initially discontinuous.

Another way of getting (22) is by using the coth function. Thus, by (18),

$$V_1 = ql\, \text{shin}\, qy\left(\cosh qx - \frac{\text{shin}\, qx}{ql}\, ql \coth ql\right)\frac{Q}{Sl}. \tag{27}$$

Noting that the first part is inoperative, the result (13) turns the last to

$$V = -\,\text{shin}\, qx\, \text{shin}\, qy\, \frac{Q}{Sl}\,(1 + 2\epsilon^{p_1 t} + 2\epsilon^{p_2 t} + \ldots); \tag{28}$$

and now, noting that the power of p is 0 in the first term, p_1 in the second, and so on, and putting $q^2 = -s^2$, we make

$$V = \frac{2Q}{Sl}\,\Sigma \sin sx\, \sin sy\, \epsilon^{pt}, \tag{29}$$

as before.

Finally, a third way. We have, by (18),

$$V_1 = ql\, \text{shin}\, qy \times \frac{\text{shin}\, q(l-x)}{\text{shin}\, ql}\,\frac{Q}{Sl}. \tag{30}$$

Now the part after the × was algebrized in §265; *see* equations (1) and (9) there. Therefore

$$V_1 = ql\, \text{shin}\, qy\, \frac{Q}{Sl}\left\{\left(1 - \frac{x}{l}\right) - 2\Sigma\frac{\sin sx}{sl}\epsilon^{pt}\right\}; \tag{31}$$

and now, on effecting the differentiations, which is done at sight by the power of p being constant in every term, we obtain (29) again. These variations will, if practised, enable the reader to operate quickly and safely.

§ **268.** Next, in further illustration of simple cases, let the line be cut at both ends. First, with an impressed force e at the point $x = y$. Then, by equations (39), (40), § 259, we have

$$V_1 = \frac{\text{shin}\, qy}{\text{shin}\, ql}\cosh q(l-x)\,.\,e, \tag{32}$$

$$V_2 = -\frac{\cosh qx}{\text{shin}\, ql}\,\text{shin}\, q(l-y)\,.\,e. \tag{33}$$

Digitized by Google

To convert to Fourier series, put $q^2 = -s^2$ in (32), and reject the part involving $\sin sx$. Then

$$V_1 = \frac{\sin sy \cos sx}{sl}\, sl \cot sl \,.\, e. \qquad (34)$$

In this use (14), making

$$V_1 = e\frac{\sin sy \cos sx}{sl}(1 + 2\epsilon^{p_1 t} + 2\epsilon^{p_2 t} + \ldots), $$

which finally makes, by the power of p being a constant in every term,

$$V_1 = \frac{ye}{l} + \Sigma \frac{2e}{sl} \sin sy \cos sx\, \epsilon^{pt}. \qquad (35)$$

This is on the right side of e. On the left side, (33) makes

$$V_2 = -e + e\frac{\cos sx \sin sy}{sl}(1 + 2\epsilon^{p_1 t} + 2\epsilon^{p_2 t} + \ldots) \qquad (36)$$

$$= -e + \frac{ey}{l} + \Sigma \frac{2e}{sl} \sin sy \cos sx\, \epsilon^{pt}, \qquad (37)$$

which only differs from (35) in the outside term expressing the steady state. The values of s are as before, but the expansion is in cosines, not sines. The summation represents the negative of the final state, which is discontinuous.

As regards the final state, we have two condensers in sequence, of permittances Sy and $S(l-y)$, with the impressed force between them. The effective permittance is the reciprocal of the sum of the reciprocals of the separate permittances—that is, $Sy(1-y/l)$. Multiplying by e we obtain the charge, and then dividing by $S(l-y)$, we obtain ey/l, the final potential on the right side of the force. On the left side it is lower by the amount e.

§ 269. We may do the effect of a single charge at y in the same way. Let it be Q, then

$$V_1 = ql \frac{\cosh qy}{\text{shin}\, ql} \cosh q(l-x) \,.\, \frac{Q}{Sl}, \qquad (38)$$

by (65), § 263, with $h = pQ$. This is on the right side of Q, and on the left side the formula is obtained by interchanging x and y. Put $q^2 = -s^2$, and reject the part involving $\sin sx$. Then

$$V_1 = \cos sy \cos sx \,.\, sl \cot sl \,\frac{Q}{Sl} \qquad (39)$$

$$= \frac{Q}{Sl} \cos sy \cos sx\, (1 + 2\epsilon^{p_1 t} + 2\epsilon^{p_2 t} + \ldots) \qquad (40)$$

$$= \frac{Q}{Sl}\{1 + 2\Sigma \cos sy \cos sx\, \epsilon^{pt}\}. \qquad (41)$$

In passing from (39) to (40) the result (14) is used, and the further passage to (41) involves only a formal change by the power of p being a constant, as in former cases.

By the last formula we see that

$$u = \frac{1}{l} + \frac{2}{l}\Sigma_1^\infty \cos \frac{n\pi x}{l} \cos \frac{n\pi y}{l} \qquad (42)$$

is a unit impulsive function existing at the point $y = x$, like (23) in fact, so that the formula (24) applies, and an arbitrary function may be expanded in cosines thus :—

$$f(x) = \frac{1}{l}\int_0^l f(y)\left\{1 + 2\Sigma_1^\infty \cos \frac{n\pi x}{l} \cos \frac{n\pi y}{l}\right\} dy. \qquad (43)$$

The introduction of the time factor ϵ^{pt}, where $p = -n^2\pi^2/RSl^2$, in the summation will, by the preceding, represent what the initial potential $f(x)$ becomes at time t later by diffusion in the cable with its ends insulated. The final state is a uniform mean potential.

§ 270. Next take a case involving a different determinantal equation. Say there is earth on at A and disconnection at B. Then $\alpha = -1, \beta = 1$. So, with an initial charge Q at $x = y$, we have, by (65), § 263,

$$V_1 = \frac{\text{shin}\, qy}{\cosh ql} \cosh q(l-x) \,.\, ql \frac{Q}{Sl}, \qquad (44)$$

in which the interchange of x and y will give V_2. Or, putting $q = si$,

$$V_1 = sl \sin sy (\cos sx + \sin sx \tan sl) \frac{Q}{Sl}. \qquad (45)$$

The first part is inoperative as regards a Fourier series. So

$$V_1 = (\sin sy \sin sx)(sl \tan sl) \frac{Q}{Sl}. \qquad (46)$$

Here we see that we have a different operator to produce the series of exponentials, viz., $sl \tan sl$ or ql than ql. The trigonometrical expansion of this function is

$$ql \text{ than } ql = \frac{2}{1 + \left(\frac{\pi}{2ql}\right)^2} + \frac{2}{1 + \left(\frac{3\pi}{2ql}\right)^2} + \frac{2}{1 + \left(\frac{5\pi}{2ql}\right)^2} + \ldots \qquad (47)$$

Remembering the meaning of q^2, namely, RSp, this makes

$$ql \text{ than } ql \,.\, 1 = 2\epsilon^{p_1 t} + 2\epsilon^{p_2 t} + 2\epsilon^{p_3 t} + \ldots, \qquad (48)$$

in the way (14) was got, only now the p's are a different set, namely, the roots of

$$\cosh ql = 0, \qquad \text{or} \qquad \cos sl = 0; \qquad (49)$$

say $sl = \frac{1}{2}\pi, \frac{3}{2}\pi, \frac{5}{2}\pi$, &c.

So, by (46),

$$V_1 = \frac{2Q}{Sl} \sin sy \sin sx\, \Sigma\epsilon^{pt}, \qquad (50)$$

which is at once transformable to

$$V = \frac{2Q}{Sl}\Sigma \sin sy \sin sx\, \epsilon^{pt}, \qquad (51)$$

by making s be constant instead of a differentiator. In this example the normal functions of the type $\sin sx$ vanish at A only. At B they have maxima, so that their slopes vanish. This is to make the current vanish at B, where there is insulation. The change in the first normal function is very great. Being $\sin(\pi x/2l)$, it is just one half of the first normal function for a line twice as long, earthed at both ends. The corresponding p is the same as that for the line of double length, so that the subsidence of the first normal system in the present case of insulation at B takes four times as long to reach a given stage, as the subsidence of the first normal system of the same line does when it is earthed at both ends.

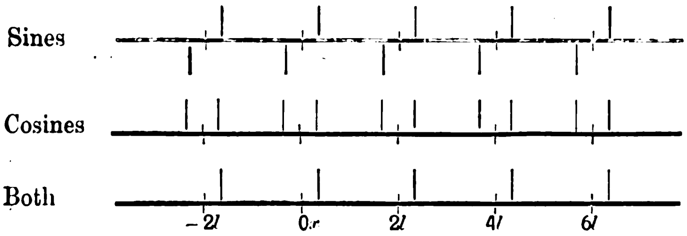
The first normal system is, of course, the most important. When t is big it is practically the only one worth counting. When t is smaller, the second one acquires significance, then the third, and so on, up to the first moment, when the whole series is required. But these Fourier series are frequently very unpractical for numerical purposes when t is taken small on account of the slow convergency.

§ 271. The above examples are sufficient to show the connection between the operational solutions and the corresponding Fourier series in the simple cases of terminal direct earth connection and complete disconnection, at least so far as the particular method employed is concerned, bearing in mind that principles are often as well illustrated by simple as by more complicated problems, if not better. The above process consists in first converting the reciprocal of the determinator shin ql or cosh ql, &c., to the sum of partial fractions by using known trigonometrical formulæ. These are easily algebrized, and the result is to give V or C or other quantity at some particular place. Thirdly, we operate on this result directly by whole differentiations, which merely means giving p a constant value in any term, and the result is the solution at any place in the form of a Fourier series.

Before passing on to another way of considering Fourier series operationally, some remarks about the functions called u above may be useful. They were considered merely as expressing unit impulsive functions located at a point $x = y$ situated between 0 and l. So far as that goes, they are quite similar. But in other respects they differ. They are both periodic, however. Every time x is increased by the amount $2l$, the sines u and the cosines u repeat themselves. But the sines u is an odd function of x, whilst the cosines u is an even function. So the sines u is negatived by changing x to $-x$. The complete meaning of the sines u is therefore an infinite row of positive unit impulses at the points $y = x, x + 2l, x + 4l$, &c., $x - 2l, x - 4l$, &c.; together with an infinite row of negative unit impulses at the points $y = -x, -x + 2l, -x + 4l$, &c., $-x - 2l, -x - 4l$, &c. On the other hand, the cosines u represents positive unit impulses at all the above places. Neither of the u's is a periodic repetition of a single impulse.

Digitized by Google

But if we take half the sum of the sines u and the cosines u, the negative impulses will be cancelled. There is left simply an infinite row of positive unit impulses at the points $y=x\pm 2nl$, where n is any integer. The diagram will serve to fix this plainly:—



The horizontal straight line is divided into equal lengths $2l$, and the vertical lines at x and $x\pm 2nl$, $-x$ and $-x\pm 2nl$ represent the distribution of the impulses in the three cases of the sines u, the cosines u, and half their sum. By (23) and (42), the new u is represented by

$$u=\frac{1}{2l}\left\{1+2\Sigma_1^\infty \cos\frac{n\pi}{l}(y-x)\right\}, \qquad (52)$$

and its meaning for our purpose is a function of y which is zero everywhere except at $x\pm 2nl$, where it is infinite, but so that its total is unity. This u is the periodic impulsive function concerned in the periodic form of Fourier's theorem. For, using (52) in (24), we have

$$f(x)=\frac{1}{2l}\int_0^{2l}\left\{1+2\Sigma_1^\infty \cos\frac{n\pi}{l}(y-x)\right\}f(y)\,dy, \qquad (53)$$

which expands an arbitrary function $f(x)$ whose values are given between the limits 0 and $2l$ into the sum of a series of sines and cosines with constant coefficients, and with a constant term expressing the mean value. Besides that, it makes the given values repeat themselves over and over again, with the period $2l$. That is, the impulse operator $\int u\ .\ .\ .\ dy$, in virtue of its periodic nature, makes $f(x)$ periodic as well.

When the period is infinitely long, if we put $s=n\pi/l$, we have $ds=\pi/l$ to represent the step from one s to the next, which is infinitely small in the limit, when the impulsive function becomes

$$u=\frac{1}{\pi}\int_0^\infty \cos s(y-x)\ .\ ds, \qquad (54)$$

and its meaning is a unit impulse at the point $y=x$ only. So, applying it through (24) to a function of y, we get

$$f(x)=\frac{1}{\pi}\int_{-\infty}^{\infty}\int_0^{\infty} f(y)\cos s(y-x)\ .\ dy\,ds, \qquad (55)$$

which is the form of Fourier's theorem applicable to any function given between $-\infty$ and $+\infty$. The mean value, should it be finite, may be considered separately.

(To be continued.)

THE EFFECTS OF LIGHTNING DISCHARGES ON UNDERGROUND CABLES.

BY C. S. DU RICHE PRELLER.

In the course of a recent inquiry into the effects of atmospheric discharges on electrical installations, the writer also had occasion to investigate the effects of such discharges on some of the underground telegraph cables laid through the St. Gothard tunnel (3,785ft. above sea level, 10 miles in length); and as the case bears on electric underground cables generally, a brief account and explanation of so interesting a phenomenon may not be out of place.

The Tunnel Cables are altogether five in number. The first two telegraph cables of 1881, supplied by Messrs. Felten and Guilleaume, were originally laid in a covered iron channel along the wall of the tunnel, about 8ft. above the rails; but owing to the rapid deterioration caused by the decomposing action of drop water charged with the products of incomplete combustion of engine fuel, notably carbonic acid, sulphurous acid, and ammonia, they were, in 1891, transferred to a trench, in which all the five cables are now embedded in alternate layers of gravel and sand, covered with granite flags and another super-

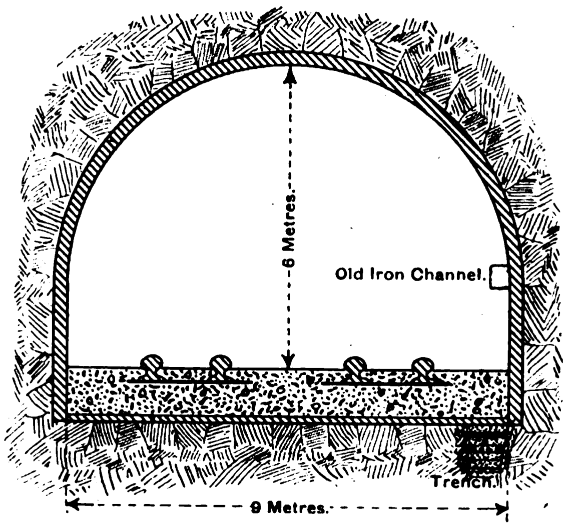


Fig. 1.—St. Gothard Tunnel. Transverse Section.

posed layer of gravel, as shown in Figs. 1 and 2.* The other three cables are the telegraph and telephone cables of 1891, supplied by Messrs. Siemens and Halske, and the telegraph

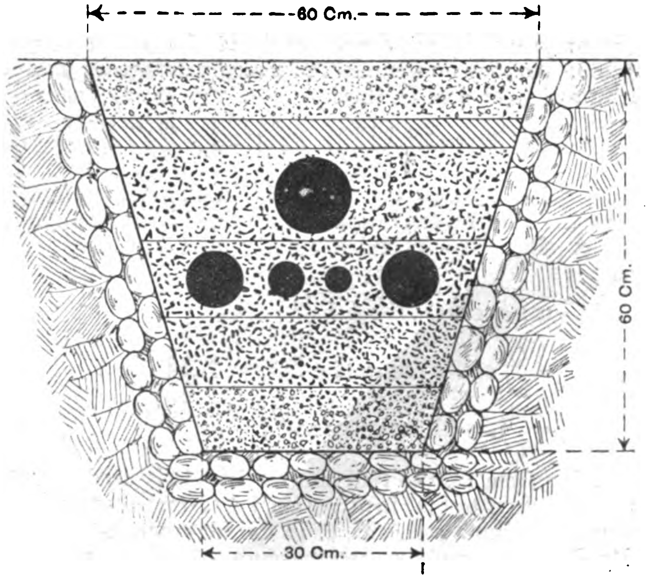

Fig. 2.—Cable Trench, St. Gothard Tunnel. Transverse Section.

cable of 1893, by Messrs. Felten and Guilleaume, which last-named was described in *The Electrician*, February 23rd, 1894.

The two cables damaged by atmospheric electricity are the railway service telegraph and concentric telephone cables of

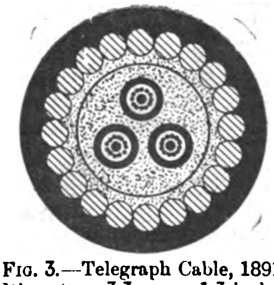

Fig. 3.—Telegraph Cable, 1891. Diameter = 3·3 cms. = 1·3 inch.

Fig. 4.—Telephone Cable, 1891. Diameter = 2·4 cms. = ·94 inch.

1891, of which cross-sections are shown in Figs. 3 and 4. The three copper conductors of the former are each 1·38mm. in

* In the Mont Cenis tunnel (7·6 miles), the conductors are still encased simply in lead pipes carried along the wall of the tunnel; in the Arlberg tunnel (6·4 miles) the trench was adopted at the outset, in 1883.

Digitized by Google

diameter. The central copper conductor of the telephone cable is 1mm. in diameter, while the metallic return consists of a conductive layer of seven 0·4mm. copper wires connected by tinfoil. Both cables are precisely similar in construction, the conductors being served with jute, upon which follows a lead mantle, then asphaltum and paper winding, then the galvanised iron-wire sheathing, and then the outer coating of asphaltum. The joints of the cable lengths (550 yards each) are protected by Siemens lead coupling boxes. The tested electrical properties of both cables were as follows:—

At 15°C. = 59°F.	Telegraph cable. Per kilom.	Concentric telephone cable. Per kilom.
Copper resistance, ohms	12	0·25
Insulation resistance, megohms..	500	250
Capacity, microfarad.......... ...	0·25	0·3

The telegraph cable is connected up to the overhead lines at the terminal stations of the tunnel (Goschenen and Airolo).

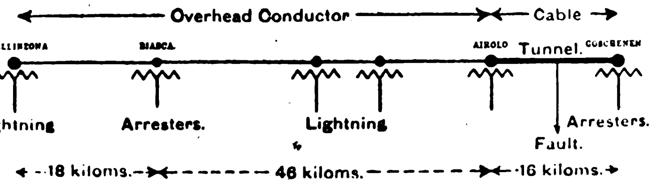

Fig. 5.

It is protected at both ends by double Siemens brass-plate lightning arresters (air-gap only 0·1mm.), each having a separate earth-plate sunk in turf-covered soil, and being, moreover, connected with the rails as well as with the water mains of the two stations respectively. The resistance to earth, tested after a spell of dry weather, was only 1·55 ohm. At Airolo Station the overhead 4mm. conductors coming from Bellinzona, 40 miles to the south, pass first through plate lightning

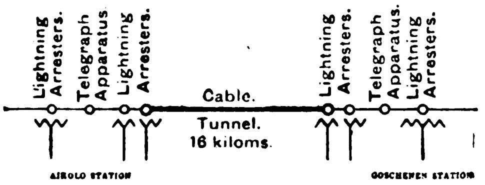

Fig. 6.

arresters and through platinum fuses 0·2mm. in diameter, then through the telegraph apparatus whose magnet coils have a resistance of 500 ohms, and thence through the double Siemens lightning arresters into the cable; and the same applies to the Goschenen station at the north end, as shown in the diagrams (Figs. 5 and 6).

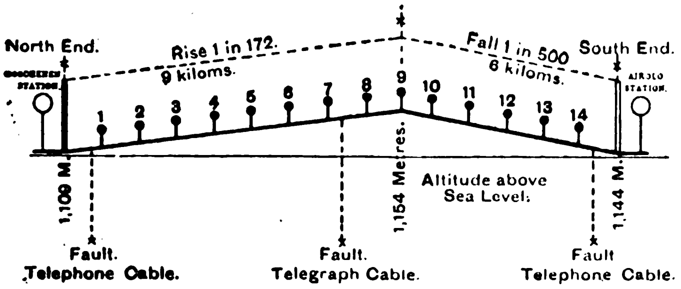

Fig. 7.—St. Gothard Tunnel. Profile.

The telephone cable connects, besides the two terminal stations, the 14 intermediate telephone stations in the tunnel, as shown in Fig. 7, the apparatus in each of them being contained in a zinc chamber. The cable is protected at both ends by Siemens lightning arresters, and constitutes, between the two tunnel termini, a self-contained metallic circuit, completely insulated from earth, and nowhere connected to overhead wires. The two cables were thus amply and carefully protected at both ends.

Damage by Lightning.—In the telephone cable, two defects, due to atmospheric electricity, were discovered last year (1894), one of them about 500 yards from Goschenen, and the other about 600 yards from Airolo, or about nine miles apart from each other. As the insulation resistance did not fall below eight megohms in each case, the defects were only discovered during one of the periodical tests, but they were in all probability due to the same discharge which damaged the telegraph cable some time before, under the following circumstances:—

On the day in question, the atmosphere was charged with electricity at both ends of the tunnel; but a thunderstorm, accompanied by a few, though by no means violent, lightning discharges, occurred only at Airolo. Soon afterwards a serious defect in conductivity was observed in one of the three conductors of the telegraph cable. Messages from Bellinzona failed to reach Goschenen, and although the conductor could still be used for local messages between the tunnel termini, two-thirds of the current were lost through leakage.

The fault was found to exist at a point nearly midway in the tunnel, or five miles from Airolo, although outwardly the cable was apparently in excellent condition, being perfectly dry, well embedded in sand, and showing no trace of damage either by chemical or mechanical action. The lightning arresters at Goschenen showed no trace of a discharge. On the other hand, at Airolo, the lightning arresters of the cable showed several black marks produced by lightning.

As regards the cable itself, it was found that at the point of leakage the inner side of the lead mantle of the damaged conductor bore a black mark about 1in. by $\frac{1}{3}$in., in the centre of which the lead had been partially melted. The jute serving between the lead mantle and the conductor was similarly blackened, and in the centre of the mark a hole about 1mm. in diameter was burnt through the jute and filled with carbonised—and, therefore, conductive—substance. On the conductor itself there was a black spot of about 1mm., on which, by aid of the lens, three punctures, produced by lightning, could be detected. The subsequently discovered damage to the concentric telephone cable in two separate places was of a precisely similar character.

Explanation of the Phenomenon.—In the opinion of the makers of the two cables, there was a simultaneous discharge at both ends of the tunnel from thunderclouds charged with electricity of the same sign, in consequence of which part of the electricity of opposite sign accumulated at the earthplates, flowed into the telegraph cable, and the two waves meeting midway of the tunnel, the insulation of the cable was unable to resist their maximum potentials at that point. According to this view, then, the damage was not due to a direct discharge.

According to another view, an oscillatory high-tension discharge occurred at one end of the tunnel, and its still higher tension midway in the cable coincided with a weak point in the insulation. As is well known, the fact that such discharges are oscillatory in character, of enormously high frequency, up to millions of alternations per second, was demonstrated by Lord Kelvin as early as 1853. Moreover, neither this nor the preceding view attempts to explain what is really the essential point, viz., why the lightning arresters failed to act.

In the writer's opinion, the phenomenon was due to a weak discharge and to the absence of impedance coils in combination with the lightning arresters. The station building at Airolo, being lower than the surrounding buildings, is not provided with lightning conductors, and this fact probably facilitated at the outset a discharge near the lightning arresters of the cable. If this discharge had been a violent one, or if it had come from the overhead lines and passed through the telegraph apparatus or the platinum fuses, the latter would have melted, and the occurrence would have attracted the attention of the officials, who, on the contrary, attributed the leakage at first to damage by mechanical or chemical agency. Experience, moreover, shows that violent and rapid atmospheric discharges have a much greater tendency to take the shortest and most direct path to earth than weak or sluggish discharges. If the discharge, after passing into the cable, had reached the lightning arresters at the Goschenen end, the self-induction of

Digitized by Google

the telegraph apparatus in that station would probably have forced it harmlessly to earth. According to Lagarde (*Ann. Tel.*, 1887, p. 418), some atmospheric discharges do not exceed 1,500 volts, and, assuming this to have been the initial tension at the lighting arresters at Airolo, the much higher tension midway on the cable was quite enough to melt the insulation, even if the lead mantle had been double the thickness. As regards the damage to the telephone cable, it could only be due either to a side discharge or to induction, or to an indirect discharge at both ends of the cable. Here again it by no means follows that there were weak points in the insulation; moreover, being a concentric cable, it is peculiarly liable to phenomena of this kind; and in this respect the case strikingly confirms Dr. J. A. Fleming's observations concerning the increased condenser effect between the inner and outer members of long concentric cables,* albeit his experiments referred only to ordinary alternating currents, and not to lightning discharges.

Confirmatory Evidence.—The writer's conclusions derive, moreover, support from the exhaustive experiments made in 1893 by H. Zielinski† for the purpose of testing the efficiency of various forms of lightning arresters, as affected by the self-induction of the telegraph apparatus to be protected. From a battery of four Leyden jars charged by an influence machine driven from an electromotor, he obtained discharges of 17,000 volts, and corresponding sparks 5mm. in length between the balls (diameter 2cm.) of a spark micrometer. The self-induction of the telegraph apparatus was represented by impedance coils of 0·094, 0·28, and 0·56 secohm, and the resistance by a water

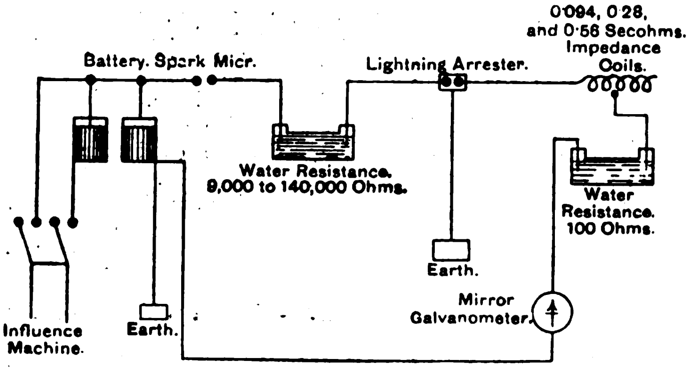

Fig. 8.

resistance of 100 ohms, while the discharges were varied by water resistances of 9,000 to 124,000 ohms, and the differences of efficiency between the full and weakened discharge were measured by a Wiedemann mirror galvanometer.‡ The arrangements of the apparatus is shown in the diagram (Fig 8).

From the results of more than 150 experiments with nine different forms of plate, comb, and spindle arresters, the writer has prepared the following table, which shows at a glance the mean efficiencies obtained, to wit, the percentage of the discharge which was forced to earth under varying self-induction of the impedence coils. The distance of the dielectric was in all cases 0·25mm.

Water resistances to weaken full discharge.	Self-induction of impedance coils.		
	0·094	0·28	0·56 secohm.
	Efficiency of lightning arresters in per cent.		
124,000 ohms	1·05	1·85	4·58
60,000 „	6·36	17·99	31·90
27,000 „	41·03	56·92	67·13
9,000 „	8[illegible]·25	86·88	91·75
0 „	100·00	100·00	100·00

* "On the Effect of Self-Induction and Capacity in Cases of Alternating Current Flow." *Journal* Inst. Elect. Eng., 1891, p. 387.

† *E.T.Z.*, 1893, p. 319, *et seq.*

‡ Similar, but more or less inconclusive, experiments were made by Lagarde (*Ann. Télégraphiques*, 1887, p. 418, and 1889, p. 32), who used a Riess air thermometer instead of a galvanometer, and in lieu of the telegraph apparatus, inserted only a water resistance of 500 ohms, thus entirely neglecting the important factor of self-induction.

It is seen that even the minimum self-induction of 0·094 secohm sufficed in all cases to obtain an efficiency of 100 per cent., viz., to force the full discharge to earth, whilst the efficiency decreased as the discharge was weakened. The experiments further showed (*a*) that the efficiency of the arresters was not appreciably affected by the earth-plate resistance, even when the latter was increased to 100 ohms; (*b*) that the result was practically the same whether the arrester was placed in the main or in a shunt circuit, and (*c*) that the efficiency of the nine different forms of arresters varied only within very narrow limits. The main factor was in all cases the effect of the impedance coil.

Conclusion.—With a view to more effectually prevent damage by lightning to the underground cables, the St. Gothard Railway Company have replaced all the original lightning arresters (*a*) by tinfoil safety fuses 4cm. (1·6in.) in length, melting at ¾ or 1 ampere, and (*b*) by lightning arresters composed of carbon blocks separated by a mica plate 0·3mm. in thickness, these arresters being intended for high-tension, and the tinfoil fuses for low-tension discharges.

It remains to be seen whether these remedies will prove effectual. It may be questioned whether impedance coils, so placed in front of the lightning arresters as to obstruct the flow of the ordinary current as little as possible, would not be preferable to safety fuses, since, in the event of an atmospheric discharge, the cable may easily be damaged before the melting of the fuses has interrupted the circuit.

Until the traffic through Alpine or other long tunnels is worked by smokeless electrical locomotives, the vitiated atmosphere due to steam traction will always render the repairs of underground cables extremely difficult and troublesome, and hence no precaution can be too elaborate. But, in the case under notice, no blame whatever can attach to the makers of the damaged cables, for neither the most careful construction of the cables themselves, nor the most perfected system of safety fuses, arresters, and earth connections, nor even impedance coils, can afford absolute protection against the vagaries of lightning discharges.

THE COST OF PRODUCTION OF ELECTROLYTIC ALKALI AND BLEACH.

A Paper on this subject has lately been contributed to the *Zeitschrift für Electrochemie* by C. Haeussermann, and is noticeable on account of the care which has evidently been taken in its composition to present, wherever possible, conclusions based on data recognised as valid in standard works treating of the alkali industry ordinarily carried on by purely chemical methods. In consequence of this claim to consideration we excerpt such passages as are needed to elucidate the basis of the estimates ultimately arrived at, and append the final summary of cost.

The calculation is based on an output of 5,000 kilos (approximately five tons) of caustic soda of 96 per cent. strength, together with the corresponding quantity of bleaching powder produced from the amount of chlorine equivalent to that of caustic soda, and necessarily resulting from the process of electrolysis. No credit has been taken for the hydrogen appearing as a bye-product of the caustic soda in the cathode compartment, as no remunerative use for it exists at present. The author parenthetically remarks that the output of alkali (by weight) per ampere-hour would be greater for potash than for soda, the difference between the molecular weights of the two alkalies (56 and 40) being comparatively large, and suggests that attention should be turned to the electrolytic production of caustic potash, a good market for which may be found up to a point at which all wants which can only be satisfied by the dearer alkali have been met. Bearing in mind, however, the comparative scarceness, and consequent high price, of potash salts, an unlimited market for caustic potash at a practicable price is not to be expected, and for the prosecution of a large staple alkali trade the use of sodium salts is a necessity. Utility is therefore served by an estimate based on the adoption of common salt, rather than of potassium chloride, as a raw material.

Digitized by Google

The first item in the estimate is energy. It is assumed that the energy will be obtained from coal through the agency of a steam engine. A working year of 350 days of 24 hours is postulated. Taking a current efficiency (as distinct from an energy efficiency) of 80 per cent., one ampere-hour corresponds with a production of 1·19 grm. of caustic soda and 1·05 grm. of chlorine, *i.e.*, 28·56 grms. and 25·2 grms. for 24 hours. For a production of 1 kilo of NaOH for 24 hours, a current of 35 amperes will therefore be requisite. The voltage needed is set down as 3·5 volts, which figure yields the result 122·5 watts for 24 hours per kilo of caustic soda. We may say that 3·5 volts is a decidedly low estimate; it is doubtful whether at least 4·5 volts would not be required in practice with any apparatus hitherto devised and tried on a considerable scale. Granting the assumed voltage, the energy needed for the production of 5,000 kilos of caustic soda works out at 832 E.H.P. for 24 hours. The equivalent quantity of chlorine liberated suffices (with allowance for loss in collection and conveyance of the gas and unavoidable imperfection in absorption by lime) to produce 12,500 kilos (12½ tons) of bleaching powder containing 35 per cent. of available chlorine. Taking 1·1 mechanical horse-power as necessary for obtaining 1 electrical horse-power, 915 H.P. must be developed by the engine driving the installation. About 85 H.P. should be added for running minor portions of the plant, *e.g.*, pumps and similar auxiliaries. About 1,000 H.P., therefore, becomes a fair estimate for the entire factory. For engines of considerable size a consumption of 0.8 kilo of coal per horse-power hour need not be exceeded, and this at the price of 1.2 mark per 1,000 kilos (say 12s. per ton) corresponds with an expenditure of 230.4 marks (£11. 10s.) for fuel burnt every 24 hours. Additional expenses, *e.g.*, those of management, lubrication and repairs, cannot be foretold with equal accuracy; but from general experience it appears that the cost of such necessary addenda may be fairly taken to equal that of the fuel. It follows that the total cost of the current necessary to set free 5,000 kilos of caustic soda (in 24 hours) is 460.8 marks (£23).

The second item in the estimate is salt. About 8,000 kilos of salt, allowing for waste, will be required, and this quantity, at 15 marks per 1,000 kilos, is equal to 120 marks. The use of brine pumped direct from the well would, of course, lower this value.

The caustic soda being obtained in dilute solution, and being in the presence of a large quantity of common salt, a considerable expenditure for evaporation has to be provided for. The liquor coming from the cathode compartments will be about 8 per cent. strength, and will amount to about 63 cubic metres per 24 hours. To get rid of the accompanying salts, evaporation of the lye to a specific gravity of 1·45 is requisite, and subsequently to this the strong solution of caustic soda must be further heated until it has become solid and the alkali is in a marketable form. Seeing that the process of evaporation is in no way different for electrolytic caustic soda from the method commonly in use, standard figures, such as those given in Lunge's classical work, may be accepted. These give the cost for 5,000 kilos of caustic soda as 60 marks. Similar remarks apply to the part of the estimate dealing with lime for the bleaching powder and with packing, these sources of expense being 112.5 and 272.5 marks (60 marks being for the packing of the caustic soda and the remainder for the bleaching powder). Labour in like manner may be taken for caustic soda at 45 marks, and for bleaching powder at 62.5 marks. The remaining labour employed about the factory (for other than attendance on the power plant) cannot be accurately computed, but may be roughly taken at 75 marks, on the basis that 25 hands are employed at an average wage of three marks. The cost of repairs to the plant (apart from the portion engaged in the production of power) must be arbitrarily assumed to equal one mark per 100 kilos of output, *i.e.*, 175 marks for the whole.

The amortisation of the capital of the factory is divisible into two heads, viz., that concerned with the buildings and that relating to the working plant. Putting the area covered by the buildings at 12,000 sq. metres, and taking the cost per sq. metre at 30 marks, the capital expended under this head would be 400,000 marks, 5 per cent. of which is 20,000 marks or 57.15 marks for 24 hours. For the plant a capital expenditure of 600,000 marks would be required, 10 per cent. on which is 60,000 marks, *i.e.*, 171.42 marks for 24 hours.

We are now in a position to put in tabular form the various items of cost for the daily expenditure of an electrolytic plant of a capacity of 5,000 kilos (5 tons) of caustic soda and 12,500 kilos (12½ tons) of bleaching powder for 24 hours.

	Marks.		£	s.	d.
Energy	460·80	=	23	0	0
Salt	120.00	=	6	0	0
Coal	90.00	=	4	10	0
Lime	112.50	=	5	10	0
Packing	212.50	=	10	10	0
Labour	182.50	=	9	0	0
Repairs (to anodes, &c.)	175.00	=	8	10	0
Amortisation	228.58	=	11	10	0
	1,581.88	=	78	10	0

To this sum the office expenses and insurance have to be added; these may be taken as 25 per cent. or more of the total expenditure. In English units the cost of producing 5 tons of caustic soda and 12½ tons of bleaching powder works out at close on £100, a sum which leaves no very great margin for profit in view of contingencies.

ON THE RESISTANCE OF GALVANIC ELEMENTS.*

BY DR. PAUL SCHOOP.

Some surprise was occasioned by a fact which was discovered in the course of some experiments undertaken by the Oerlikon Company and the author before setting up a secondary battery at the central tramway station in Hirsland-Zurich. The battery, which was arranged in series, consisted of 300 cells, each containing three positive and four negative plates, having a resistance on open circuit of $300 \times 0·005$ ohms $= 1·5$ ohm. With a discharge of 20 amperes a fall of potential of $20 \times 1·5 = 30$ volts, due to the internal resistance of the battery above, was to be expected. The result, however, did not bear out this anticipation, but proved more favourable to the battery considered as a transformer, since, with a discharging current of 20 amperes, the potential difference merely fell 7-10 volts—*i.e.*, only one-third of the calculated amount. This circumstance led the author to experiment on the resistance of cells when a current is passing.

It was found by Kohlrausch's method, which is applicable when no current is passing, that the resistance of a discharged cell was greater than that of a charged one. The resistance of a cell left standing on open circuit increases continuously, and this is probably due to the formation on the plates of lead sulphate, which is a very bad conductor. In the case of a freshly-charged cell, left standing on open circuit, the resistance decreases first, which may arise from the plates, on the breaking of the circuit, being saturated with rather concentrated sulphuric acid, which is a worse conductor than the more dilute 30 per cent., and also from the presence of gas in and on the layers of active material, which may contribute to the rise of resistance by diminishing the contact of the electrodes with the electrolyte. The resistance of the cells on open circuit depends on the strength of current employed in charge and discharge, as well as on the temperature and the concentration of the dilute sulphuric acid. The resistance varies with the electrical condition of the electrodes, and these, as already mentioned elsewhere, vary with time. When a cell is examined from time to time, it is generally found that the resistance has altered slightly between each measurement. The resistance of a cell on open circuit is lower the nearer the plates are placed together, the greater their surface, and the higher the temperature of the cell; and is lowest in new cells at the commencement of their use. It varies in cells in commercial use between 0·0001 and 0·02 ohms, the cells with large plates having very low resistance, while that of cells with small plates is proportionately higher.

The resistance of a cell can be approximately estimated by observing its potential difference with different large charge and discharge currents. If the cell had no resistance, and if the influence of the separated ions on the electromotive force were independent of the current density, the cell would maintain the same potential difference for wide variations in the strength of current during charge and discharge. But if there is an ohmic resistance in the cell, then on an increase in the current during discharge (discharge is better than charge for this purpose) the decrease in potential difference will be equal to the quotient of the resistance of the cell by the strength of current passing through it. The observations of potential difference were made with a dead-beat D'Arsonval

galvanometer, the mirror of which came to rest within a second after making contact. A cell with Tudor plates was discharged, the current being kept constant by a suitable adjustment of the resistance of the circuit. The discharge lasted six hours. Every 15 minutes first the potential difference was noted, then for two seconds the discharge circuit was broken, and the galvanometer readings observed. At the moment of breaking the deflection increased, and remained stationary, so that the reading could be taken; then the circuit was again closed and the discharge continued at a constant rate (35 amperes).

Table I.‡

Time in minutes.	Terminal potential during discharge.	Potential difference on open circuit.	Difference.
0	394	408	14
15	397	409	12
30	397	408	11

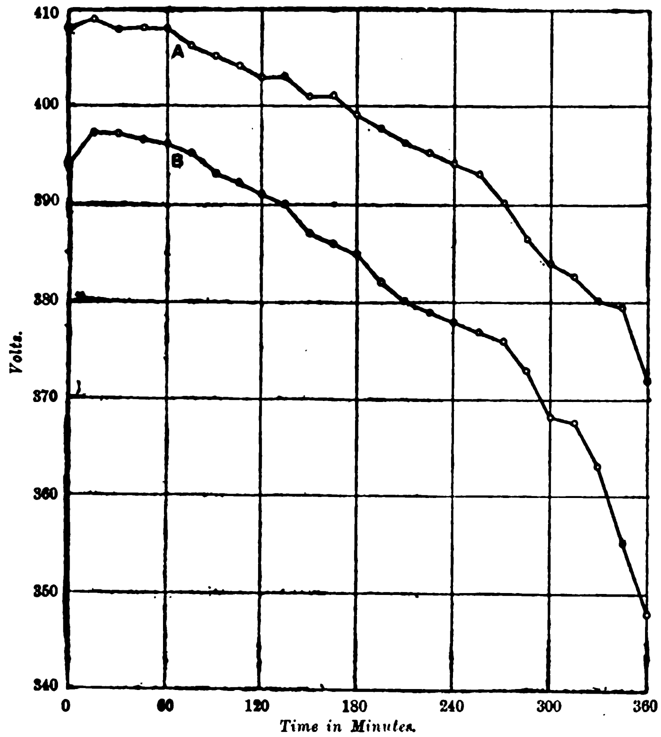
330	363	380	17
345	355	379·5	24·5
360	348	372	24

The numbers divided by 200 give the potential difference in volts. The resistance of the battery at rest was about 0·005 ohm, the resistance of the galvanometer was about 10,000 ohms. The



Curves plotted from Table I. A = Curve connecting Time and P.D. on open circuit. B = Curve connecting Time and Terminal Potential during discharge.

density of the sulphuric acid was 1·18 at the beginning of discharge, the temperature of the room was 15°C., the distance between the plates was 12mm.

‡ We have taken the liberty of plotting the observations contained in these tables in the form of curves.

The following table (II.) gives the discharge of the same cell with a current of 62 amperes after it had been recharged with a current of 35 amperes, until gas was given off at both electrodes. Between the completion of charge and the beginning of discharge there was an interval of 12 hours' rest. It may be assumed that the electrical

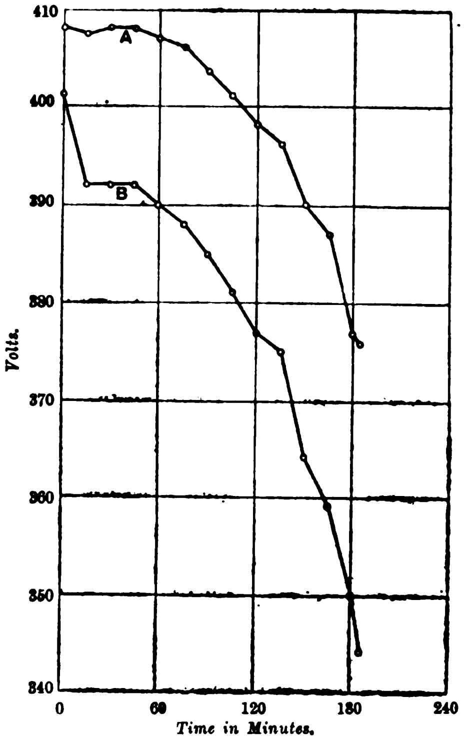
165	359	387	28
180	350	377	27
185	344	376	32

conditions of the cell during this discharge did not materially differ from those in the preceding case. The increase in the current is 27 amperes. Now, on comparing the potential difference for the



Curves plotted from Table II. A = Curve connecting Time and P.D. on open circuit. B = Curve connecting Time and Terminal Potential during discharge.

times at which the capacity condition of the cell is the same, as for example, at 30 or 60 ampere-hours discharge, the following points may be noted (Table III.):—

Table III.

Discharge in ampere-hours.	Terminal potential at 35 amperes.	Terminal potential at 62 amperes.	Difference.	Resistance in ohms.
31	396	392	4	0·00074
62	390	390	2	0·00037
93	386	385	1	0·00018
124	380	377	3	0·00055
155	376	364	12	0·00222
186	367	350	17	0·00315

It appears that the resistance of the cell differs in amount, and is lowest when it is half discharged. Beyond that point the resistance increases, and reaches about 17 times its minimum value.

Digitized by Google

But as already mentioned, these figures do not quite correspond with the truth, for it would have to be assumed that the E.M.F. of the cell was constant during the whole of the discharge, which is not the case. Now the influence of the decrease of E.M.F. is entirely eliminated in both sets of experiments if one may assume that the decrease in both experiments is the same with regard to the ampere-hours discharged. This, however, is not quite the case, as the decrease of the E.M.F. is greater under corresponding conditions with a higher rate of discharge than when a lower rate has been employed. The calculated values of the resistances given above, therefore, are somewhat too high towards the end of discharge. The resistance of working batteries is therefore subject to very considerable variations, and during discharge at certain periods are many times smaller than those batteries on open circuit.

F. Streintz has already investigated the resistance of a cell with Tudor plates during charge and discharge, but did not examine closely its distribution on the individual electrodes. The method employed by the latter is not open to the objections which can be made to that used by the author, which does not separate the resistance from the potential difference of the cell. In spite of that the results obtained by these two different methods are in the main the same: they both throw light on the fact which was observed at the central station, and which at first seemed remarkable. The determination of the resistance occurring at the electrodes is all the more difficult, because Fuchs' method is not at all free from objection when it is used for the determination of potential difference in a closed circuit. For a closer confirmation of what has been stated readers may be referred to the recently-published work of the writer's on "Secondary Batteries," Part I. (Halle: W. Knapp).

ELECTRICITY AT THE NEW YORK NAVY YARD.*

The great extent to which electricity is employed in the new warships of the United States Navy would naturally lead one to infer that at the New York Navy Yard, where the principal naval electrical depot is located, there would be an extensive electrical establishment. This, however, is far from being the case, owing doubtless to the parsimony of Congress in its appropriations for other than the most pressing necessities of the naval service. Even in the electric lighting of its great workshops the Navy yard is behind the meanest private establishment, notwithstanding the pressure brought to bear on each successive Congress by the Secretary of the Navy for appropriations necessary to purchase and instal a plant of the necessary character and capacity.

The machine shops aboard all of the larger men-of-war afford facilities for ordinary electrical repairs, thus relieving the yard shops to some extent. Aside, however, from repair work and the calibration of instruments, an important function of the yard electrical department is in the inspection and testing of electrical naval supplies and machinery, the exigencies of the service requiring that nothing shall pass into use until its reliability has been thoroughly established by the most rigid tests or inspection.

In the machine shop are lathes, shapers, milling machines, &c., driven ordinarily by a small steam engine. A 12-kilowatt Edison dynamo is belted to the line shaft which transmits power to the machine tools, and under ordinary circumstances this dynamo furnishes current for lighting the shops and testing rooms. In case it becomes inexpedient for any reason to run the steam engine, the lighting circuit and dynamo are connected up with the Navy yard street mains, the dynamo then being used as a motor to drive the machinery.

The current for heavy testing is supplied by the direct connected equipment imported from abroad, consisting of a Siemens generator of 80 volts and 400 amperes capacity, and a 40 H.P. Belliss double cylinder vertical engine.

For lighter work a smaller outfit is used, consisting of a 2 kilowatt General Electric dynamo direct driven by a Case engine. Both of these equipments, as well as the machinery above mentioned, are placed on substantial foundations entirely separate from the floor and foundations of the building so as to avoid transmitting any jar or vibration to the balance room.

Ten per cent. of each lot of lamps is tested, and in the event that 30 per cent. of the lot fails to come up to specifications the entire shipment is rejected. The insulation test consists in immersing the wire in salt water 24 hours, then submitting it to heat at 200°F. seven hours a day for seven days, and finally giving it another salt water bath for 24 hours. Wire intended for 110-volt circuits is tested between each bath and the baking under a pressure of 300 volts, and is rejected unless the insulation shows a minimum resistance of 1,000 megohms per nautical mile throughout the series of tests. The baking is accomplished by placing the coil of wire in the centre of an oven, the walls, floor, and roof of which are covered on the interior with steam pipes. The coil of wire is supported on blocks so as to avoid contact with the hot pipes.

Among the multitude of supplies, instruments, &c., in the store room are to be found direct-connected marine electric lighting sets, electric projectors, and electric engine signalling apparatus. The latter interesting device is to transmit signals from bridge to engine room on board ship, replacing the gongs and pull wires commonly used for that purpose. The mechanism in the engine-room is a duplicate of that on the bridge. In practice the officer on the bridge pulls the handle over to the right or left, according to the direction in which he wishes the vessel to be propelled, until the pointer attached to the handle indicates the speed at which it is desired to run the engines. The needle of the engine room apparatus moves in synchronism with the lever on the bridge, pointing out the speed and direction desired. The signal is acknowledged from the engine room by moving over the handle there until its pointer coincides with the signalling needle, which has the effect of moving the needle of the apparatus on the bridge exactly as the needle in the engine room was moved. Thus, both engineer and pilot have a constant indication of the speed and direction of the engines.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) **FRIDAY, June 7th,**

ROYAL INSTITUTION.

9 p.m. Friday Evening Discourse: "Phénomènes Physique des Hautes Régions de l'Atmosphère," by Prof. Alfred Cornu, F.R.S.

MONDAY, June 10th,

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

SOCIETY OF ENGINEERS.

7:30 p.m. Ordinary Meeting at the Royal United Service Institution, Whitehall. The following Paper will be read: "Safety Appliances for Elevators," by Herbert W. Umney.

TUESDAY, June 11th.

ELECTRICAL TRADES' SECTION.

12 (noon). Meeting of the Section at Botolph House, Eastcheap, to consider the new Board of Trade Regulations.

FRIDAY, June 14th,

PHYSICAL SOCIETY.

5 p.m. Meeting at Burlington House. The following Papers will be read: (1) "The Measurement of Cyclically Varying Temperatures," by H. F. Burstall; (2) "The The Thermal Constants of the Elements," by W. F. Deerr; (3) "An Electromagnetic Effect," by F. W. Bowden.

Alternate-Current Dynamo Electric Machines.—At a recent meeting of the Royal Society, Dr. J. Hopkinson and Mr. E. Wilson read a Paper on this subject. The Paper deals experimentally with the currents induced in the coils and in the cores of the magnets of alternate-current machines by the varying currents in and the varying positions of the armature. It is shown that such currents exist, and that they have the effect of diminishing to a certain extent the electromotive force of the machine when working on resistances as a generator without a corresponding effect upon the phase of the armature current. It is also shown that preventing variations in the coils of the electromagnet does not, in the machine experimented upon, greatly affect the result, and that the effect of introducing copper plates between the magnets and the armature has not a very great effect upon the electromotive force of the armature, the conclusion being that the conductivity of the iron cores is sufficient to produce the main part of the effect. A method of determining the efficiency of alternate-current machines is illustrated, and the results of the experiments for this determination are utilised to show that in certain cases of relation of phase of current to phase of electromotive force, the effect of the local currents in the iron cores is to increase, instead of to diminish, the electromotive force of the machine. The large majority of the experiments described were made in the summer of 1893, and a considerable part of the Paper was then written. The authors were assisted by Mr. F. Lydall, one of the student demonstrators at King's College at that time.

SPECIAL NOTICE.

Owing to the growth of the electrical and allied industries the demands for space in "THE ELECTRICIAN" are, for the greater part of the year, so pressing that a permanent increase in the size of the journal has become necessary. To meet the increased cost involved by this step, and by other improvements, such as heavier paper and more numerous illustrations, the price of "THE ELECTRICIAN" has from May 3rd been advanced to 6d.

The Subscription to "THE ELECTRICIAN," commencing with Vol. XXXV. (May 3, 1895), is as follows:—

	YEAR.	HALF-YEAR.	QUARTER.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

NOW READY.—Vol. XXXIV. of "THE ELECTRICIAN," bound in strong cloth. Price 12s. 6d., post free 13s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

THE TELEPHONE INQUIRY.

When a Government is in want of a policy, or a minister in want of a cue, it is usually sought for inside one of the Parliamentary Committee rooms. The device is not generally esteemed very dignified, and is often only a roundabout way of shelving the subject altogether. None of these things, however, can be said of the Parliamentary inquiry which has just completed its examination of witnesses in respect of the telephone service and its relations with the State. The report may take probably a considerable time to prepare, if the voluminous evidence is to be impartially weighed and digested; or it may be got ready very quickly if, as might happen, the Committee are unable to offer any definite recommendation except for the publication in full of all the evidence tendered. On the whole, we are in that position ourselves, and we make no apology for offering some comments at this stage of the case, feeling sure that nothing we can say one way or the other will affect the broad conclusions to be drawn from the numberless suggestions and inexhaustible statistics placed at the Committee's disposal.

One of these conclusions certainly is that the public will learn to set a more correct estimate on the value of opinions proffered by self-chosen advocates of particular and novel schemes of telephonic administration. For knocking the bottom out of irrepressible faddists there is nothing so sure as a public inquiry; and it must be said of this one, to its

Digitized by Google

credit, that not a few personages who thought themselves authorities have left the Committee room emptied of their reputation, if not of their conceit. It is very easy to collect any number of complaints against the telephone system—or, for that matter, against any human system whatsoever; but when men come forward with schemes of reform they should at least take the trouble to understand something of what they are talking about. Representatives of municipalities, who are greatly to the fore just now, are very much lacking in this respect; and the National Telephone Company's contention that its business would be worked less efficiently by municipal bodies than by private enterprise found no little support in the character of the testimony offered by typical members of the former. Not excepting the "evidence" tendered by that superfine organisation the London County Council, the municipal witnesses were, we must admit, far from showing any special capacity for working the telephone. In point of fact, the major part of the witnesses failed to grasp the true problem to be solved, namely, how to convert an imperfect telephone system into one corresponding with that of the perfected telegraph system which exists in Government hands. None but the official witnesses fully realised this point—the only one indeed worth considering. What the telephone has suffered from hitherto has been, it may be confidently asserted, a species of parochialism, gradually, it is true, developing on a bolder and more national basis, but still hampered and afflicted by the petty and narrow limitations under which its early years were spent. Nobody is particularly answerable for this; railways grew up in a similar way. Telephones were for a good while supposed to be merely elongated speaking tubes, serviceable for purely local purposes. The plans, therefore, were localised; and if they do not fit in very well with the larger requirements which have arisen in these days, nobody can wonder at it. The latest understanding arrived at by the Post Office with the National Telephone Company is a frank admission that competition over the same area is not merely inexpedient but impossible, and the State merely claims the trunk lines as being part and parcel of its main telegraph system. Co-operating in this way it is not unlikely that the Company's administration will go on improving to the level of the one administered by the State; and whether the whole may finally fall into the hands of the Post Office will depend very much on how far this dual arrangement contrives to work harmoniously to the satisfaction of the public. There is no half-way house between State acquisition and State abstention, except possibly that which has been already arrived at.

Of the many "progressive" suggestions which came out into the light in the Committee room, none was more prominent than that of municipal telephones. The supporters of this latest development of municipalisation did not, as we have before remarked, cut a very impressive figure. Against the running of local telephone exchanges by local authorities there is the very obvious argument that where the Government itself has failed to compete successfully with the company which at present holds the field no municipality, however powerful, could possibly succeed. The same considerations which have prevented the State from pursuing a competitive game, namely, the taxpayers' pockets, might be expected to operate in the case of local authorities. There is, however, something to be said in favour of the practicability of municipal telephony. England and Scotland afford many striking examples of what can be done municipally wherever a strong municipal spirit is in existence. When two companies compete in the same town telephone users are moved to cast in their lot with one or the other by purely business motives; the concern which can induce the public to believe that it offers on the whole the better service will win, and the advent of the day of victory will be hastened by the innumerable petty vexations inherent to the rivalry of the two exchanges. But given the existence of a real grievance against the telephone company and an able municipality backed by a powerful municipal spirit, and we should be sorry to risk the dogma of editorial prescience and omniscience by dogmatically predicting disaster. With the magnificent network of trunk wires on its hands, the National Telephone Company was, indeed, in an impregnable position; but to-day the trunk wires are open to all comers and municipal telephony has as good a chance as it is ever likely to have. Whether it is economically expedient or morally right to adventure the ratepayers' money in such a campaign of competition is a big question, which we need not now discuss. All we contend is that municipal telephony cannot be contemptuously dismissed as utterly impracticable, and that one single successful instance of it would in all probability save the necessity of a second.

One of the most useful pieces of evidence furnished to the Committee was that by Mr. STAATS FORBES, the President of the National Telephone Company, giving statistics of users and charges for this and other countries where the telephone is in popular demand. We have never been the apologists of this Company; but we gladly admit that the figures adduced by its able representative before this Parliamentary Committee go far to exculpate the management from many of the accusations which have been freely hurled against it for many years past unchallenged. Compared with those of other countries, its charges are not higher, and its services are not less efficient or popular when the national conditions are fairly taken into account. No importance can be attached to statistics of complaints against this one company, seeing that no corresponding efforts have been made to obtain similar figures from other countries. If a round-robin could be got from all quarters we suspect that a majority could be obtained for voting the telephone an unmitigated nuisance which everybody would wish to see abated, and perhaps even abolished altogether. And this, not because of its defects, but by reason of the demands it makes on the nervous energies of its users. But it is too late to consider their nerves; the only question is the efficiency of the service; and obviously this can best be obtained by a system which is virtually controlled by one administration.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(Continued from page 161.)

40. Kennelly's Break Test *(continued).*—In tests to false zero it is important to put the resistance added to the battery circuit between the bridge and key, and to have the earth connection direct on the other side of the key. The polarisation current from the cable when the testing key is released flows partly through the galvanometer and third arm of the bridge to earth, and is partly shunted past the galvanometer through the ratio arms and across the key. By putting the resistance between bridge and key it augments the resistance of the shunt circuit and makes the galvanometer more sensitive to the false zero current; whereas, if put between key and earth, it would be directly in the path of the current through the galvanometer, and thereby reduce the sensitiveness of the latter.

Digitized by Google

The following example of a Kennelly break test may be useful:—

Battery used had internal resistance 72 ohms and E.M.F. 40·5 volts.

Ratio of bridge, 100/1,000; therefore $a = 100$ and $\mu = 10$. The resistance to add to battery for a given current in milliamperes to line was found by

$$\left(\frac{\mu}{\mu+1}\right)\frac{1{,}000\ E}{\text{milliamperes}} - \left(b + \frac{\mu a}{\mu+1}\right) - \frac{\mu}{\mu+1}R.$$

In this case:

$$\frac{\mu}{\mu+1} = \frac{10}{11}.$$

$$b = 72$$

$$\frac{\mu a}{\mu+1} = \frac{10}{11} \times 100 = 91$$

$$\frac{\mu}{\mu+1}R = \frac{10}{11}R.$$

The formula is therefore $\dfrac{36{,}818}{\text{milliamperes}} - 163 - \dfrac{10}{11}R.$

Now, as R is the resistance measured on bridge with a given current to line, the value of $\frac{10}{11}$ cannot be known till a preliminary reading is taken, with the approximate added resistance found by the first two terms of the above formula.

For one milliampere the approximate added resistance

$$= 36{,}818 - 163 = 36{,}655 \text{ ohms.}$$

For two milliamperes,

$$\frac{36{,}818}{2} - 163 = 18{,}246 \text{ ohms.}$$

For three milliamperes,

$$\frac{36{,}818}{3} - 163 = 12{,}109 \text{ ohms.}$$

	Ohms.		Ohms.
For 4 milliamperes......	9,041	For 12 milliamperes ...	2,905
„ 5 „	7,204	„ 16 „ ...	2,138
„ 6 „	5,973	„ 20 „ ...	1,679
„ 8 „	4,439	„ 24 „ ...	1,371

Adding the first approximate resistance for one milliampere (36,655 ohms), the balance obtained was 992 ohms (R).

The added resistance was therefore reduced by

$$\frac{10}{11} \text{ of } 992 = 902 \text{ ohms.}$$

Putting 35,753 ohms in, the test was taken again, balance being 990 ohms, which was taken as the correct resistance of cable up to break, plus resistance of break, with 1 milliampere.

For 2 milliamperes the approximate resistance, 18,246, was first reduced by 900 (judged from last test). The balance was then 800 ohms, $\frac{10}{11}$ of which = 727. The resistance, 18,246, was then reduced by 727 ohms, and a balance obtained of 802 ohms, which was the resistance of cable up to break, plus resistance of break, for 2 milliamperes. The same thing was done through all the above currents, except that after a few more readings the value of $\frac{10}{11}$R could be judged sufficiently nearly from the reading immediately preceding. The readings observed were as follows:—

	Ohms.		Ohms.
For 1 milliampere	990·0	For 8 milliamperes ...	625·0
„ 2 „	802·0	„ 12 „	600·0

„ 4 „	690·0	„ 20 „	582·0
„ 5 „	664·0	„ 24 „	575·0
„ 6 „	649·0		

Six pairs (in which the currents were as 1 : 4) were worked out from these results by the formula given above,

$$B - (A - B) = \text{Distance of break in ohms,}$$

where B and A are the results obtained with currents in the proportion of 4 to 1 respectively.

1st Pair (Currents 1 and 4).

A =	990
Subtract B =	690

	390
	448
	471
	485
	500
	501
	6)2,795
Mean	466 ohms.

The actual distance of the break was afterwards found to be 470 ohms. The mean of the 2nd, 3rd, and 4th pair which gave the closest result was:

	448
	471
	485
	3)1,404
Mean	468 ohms.

It will be seen that the resistance of the break itself varied from 520 ohms with one milliampere to 105 ohms with 24 milliamperes.

The false zero is sometimes taken as half the swing of the galvanometer from instrument zero, the swing being taken immediately on releasing the battery key.

41. Battery E.M.F. by Varley Slides.—The slides being useful for the above tests, it may be desirable to briefly explain their use. By using them the galvanometer is balanced to zero, which is a great consideration on board ship.

The action is best explained by reference to the potentiometer. This is simply a stretched wire A B (Fig. 112) of uniform section and any convenient length, say one yard, throughout the length of which is an accurately divided scale. A current being passed through the wire, say from A to B, we have a certain difference of potential between the ends, which is distributed uniformly per unit length of the wire as shown by the dotted lines. For instance, if A B is divided into a number of equal parts the potential at, say, the point 8 is eight times that at point 1, twice that at point 4, and so on.

Without knowing the current flowing through the wire or its resistance, we can, by means of a standard cell, find the potential at one point on the wire, from which the potential at all other points can be found.

The negative pole of the standard cell is connected to the negative end B of the wire, and the positive pole to a galvanometer and key. If the free end of the wire is now placed in contact with the wire A B and moved along it (the key being closed) a position will be found where no current passes through the galvanometer.

The E.M.F. of the standard cell is then exactly balanced by the opposing potential in the wire, and therefore the potential at this point is equal to that of the standard cell. Supposing

Digitized by Google

the balace obtained with the movable wire was at 0·7 on the wire A B, with a standard cell of 1·4 volt; we know then that the potential along A B is

$$\frac{1\cdot4}{\cdot7} = 2 \text{ volts per division.}$$

Now we may replace the standard cell by any battery whose E.M.F. we require to measure. If the point of balance with the battery is at 9, as in Fig. 113, the E.M.F. of that battery is 18 volts, and if at, say, 7·75 the E.M.F. is 15½ volts, and so on.

It is not necessary to know the E.M.F. or resistance of the battery that produces the current in A B. It must, however, have an E.M.F. greater than that of the battery balanced against it.

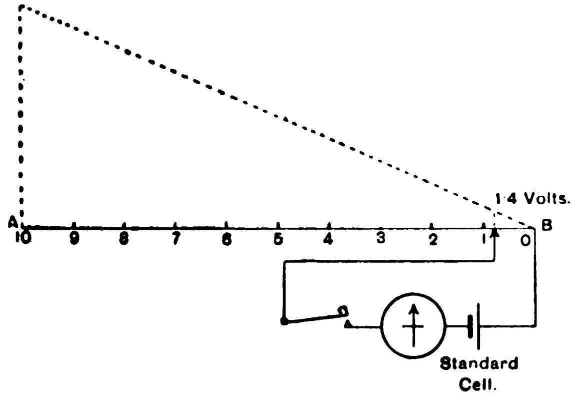

Fig. 112.

For the sake of distinction, let us call the battery which produces the current in the wire the "spare battery," and that whose E.M.F. is being measured, the "test battery" (Fig. 113). The wire potentiometer cannot be used for more than moderate voltages with the high-resistance cells used in cable testing, because the wire would have to be of higher resistance, smaller diameter, and longer length than practicable, in order to get sufficient range of potential.

The resistance is made as high as possible by the use of a wire of platinum alloy of high specific resistance, and in some instruments three, four or more lengths are employed connected in series. The wire must also be of small diameter to bring up the resistance, but it is not possible to carry this very

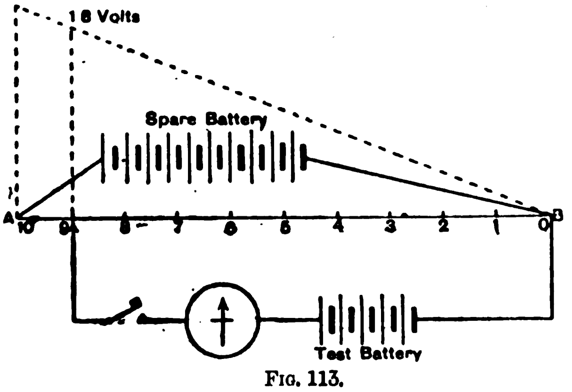

Fig. 113.

far, as the contacts made on the wire in course of time lessen ts diameter in places, and slight inequalities of section have more effect in wires of small diameter. When a high resistance potentiometer is necessary it must be constructed of independent coils of wire connected in series.

But in any such series of coils there is not the fine adjustment that can be got with a wire. On the wire contacts can be made so close together that the point of balance can be obtained exactly, but in a series of coils we cannot get nearer than the difference of potential per coil. On one contact the balance might be out by a deflection to the left, and on the next by a deflection to the right, and there would be no means of getting between. The number of coils might be increased, but it is not practicable to increase their number to any considerable extent, or to sub-divide them into a sufficiently large number of small coils.

Mr. Varley has met this difficulty by the arrangement of resistance coils known as slides. With only 201 coils 10,000 sub-divisions can be obtained.

In order to explain the action of the slides, let us take a simple case of 21 coils, which can be divided in the same way into 100 equal parts.

Let A B (Fig. 114) consist of 11 coils of equal resistance, and C D 10 coils. Let the whole resistance between C and D be equal to that of two coils on A B. Let there be two contact pointers E and F connected to the ends of C D, rigidly connected together, but insulated from each other. These can be moved along A B so as to enclose any pair of coils. It is evident that between the pointers E and F the resistance to any current flowing between A and B is equal to one only of the coils on A B, since the two coils between the pointers are shunted by an equal resistance.

The potentials produced by the spare battery connected to A B are shown by the dotted lines. Between E and F there is the same fall of potential as on any single coil on A B outside the pointers, and the fall of potential at the ends of any pair of coils on A B between the pointers E F is subdivided into 10 parts along C D. And since the resistance

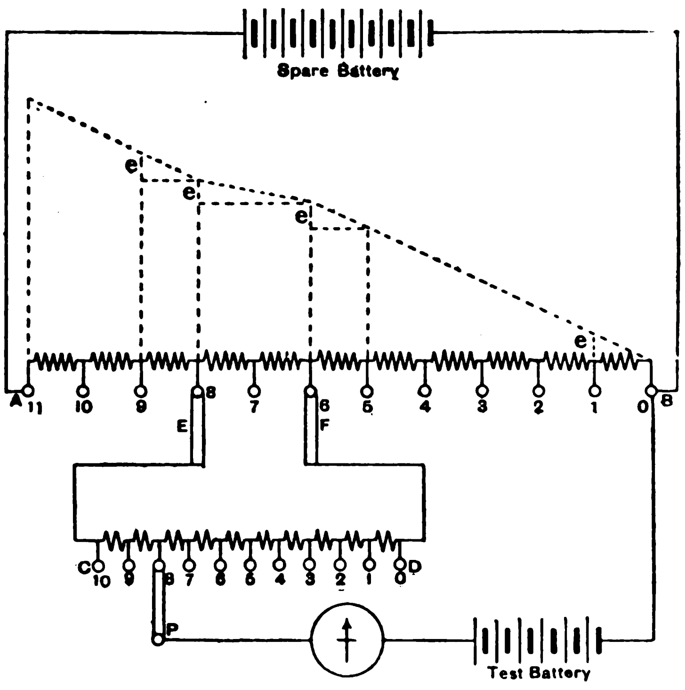

Fig. 114.

between the pointers in any position is equal to that of one coil on A B, and the pointers can be moved anywhere on A B, it follows that we have the same thing as if each coil was divided into 10 parts, giving a total number of 100 divisions.

Suppose a test battery connected up as shown in Fig. 114 to this small set of coils, and that no current passes through the galvanometer when the pointers are in the postions shown, namely, F at 6 and P at 8. The E.M.F. of this battery will then be 68 times the difference of potential per division.

By substituting a standard cell in place of the test battery, we have, say, F at 0 and P at 7 when no current passes through the galvanometer.

If the E.M.F. of the standard cell is 1·4 volts, we have then

$$\frac{1\cdot4}{7} = 0\cdot2 \text{ volt per division,}$$

and the E.M.F. of the battery tested is

$$68 \times 0\cdot2 = 13\cdot6 \text{ volts.}$$

The small resistance C D acts as a vernier to the large resistance A B, and as the vernier can be moved to all parts of A B it practically divides each coil on A B into 10 equal parts, making 10 × 10 = 100 divisions of the entire resistance.

Digitized by Google

In Varley's slides there are 100 coils in C D and 101 in A B, the extra coil being, as before, to make up for the shunted pair of coils, which are equal in resistance to one.

It is possible, therefore, in the slides to divide the potential into $100 \times 100 = 10,000$ equal parts. The resistance of the coils on A B is 1,000 ohms each, making 100,000 ohms for the whole.

The vernier set of coils C D consists of 100 coils of 20 ohms each, making 2,000 ohms, equal to two coils on A B.

There are two ways of measuring the E.M.F. of a battery by the slides as follows:—

(1) By connecting an independent spare battery to the slides, and balancing with standard cell; then putting the battery, whose E.M.F. is to be measured, in the place of the standard cell, balancing again and comparing the two readings on the slides. The connections are as in Fig. 115.

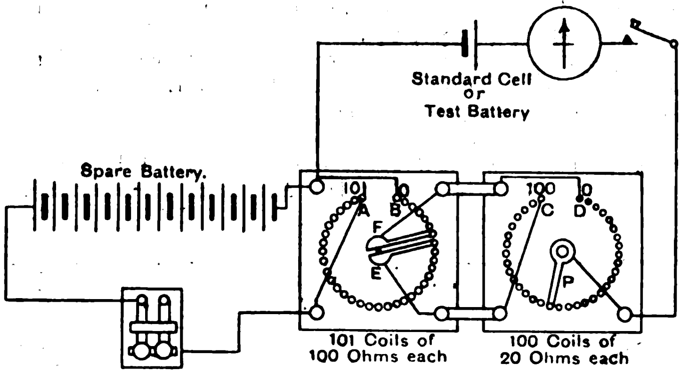

Fig. 115.—Slides.

The fall of potential over the resistance of the slides, produced by the independent battery is shown in Fig. 116. The E.M.F. of this battery must be greater than that of the battery to be tested.

One balance is obtained with the standard cell connected as shown in the figure; then the cell is removed, and the battery to be tested connected up in its place, and a second balance obtained on the slides. The double pointers are moved first to the nearest position to balance, and then the single pointer to get the balance exactly. Balance is obtained when both battery circuits are closed by the keys and the galvanometer remains at zero.

In reading the slides the following should be observed:—

Read first from the double pointer, taking the figure from the pointer nearest zero. Multiply this by 100 and add the reading on the single pointer.

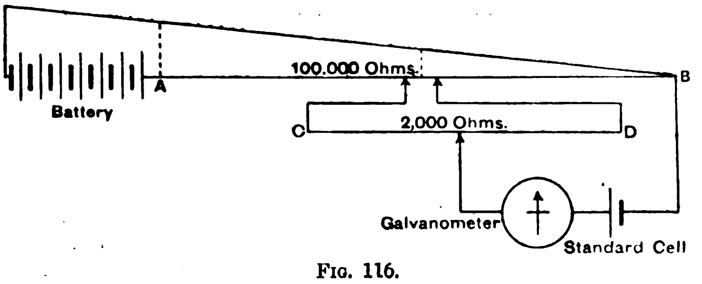

Fig. 116.

For example, say the standard cell is balanced when the pointer nearest zero (of the double pointer) is at 2 and the single pointer is at 74. Also that they are respectively at 87 and 8 when the battery is balanced in place of the standard cell. The readings are then respectively 274 and 8,708, and if the standard cell is 1·4 volts the E.M.F. of the battery is

$$1{\cdot}4 \times \frac{8708}{274} = 44{\cdot}5 \text{ volts.}$$

This method is absolutely accurate, but it requires an independent or spare battery on the slides, which may not always be available.

(2) The second method is without an independent or "spare" battery. In its place is put the battery whose E.M.F. is to be tested, that is direct on the slides, between terminals 0 and 101 on the large coils A B. The connections are otherwise the same, and one balance only is required, namely, with the standard cell connected, as in Fig. 115.

Suppose the reading with the standard cell balanced to be 315. Then the E.M.F. of the battery is

$$1{\cdot}4 \times \frac{10,000}{315} = 44{\cdot}5 \text{ volts.}$$

This result is really the difference of potential at the battery terminals, but, owing to the high resistance of the slides (100,000 ohms), only differs from the actual E.M.F. by an inappreciable amount. Strictly, the above result should be increased by the fraction

$$\frac{\text{battery resistance}}{100,000}$$

of the whole to give the E.M.F.

For example, with a battery of 100 ohms the amount to add would be

$$\frac{100}{100,000} \times 44{\cdot}5 = {\cdot}0445 \text{ volt,}$$

which would make the E.M.F. only 44·54 instead of 44·50, or an error of only $\frac{1}{10}$th of 1 per cent. Even with a battery of as high a resistance as 500 ohms the error is only 0·22 volt or an error of $\frac{1}{2}$ of 1 per cent.

The above correction can, however, be applied when the resistance of the battery has been measured; but it will be seen that in most cases it is inappreciable and certainly negligible when the battery resistance does not exceed 100 ohms.

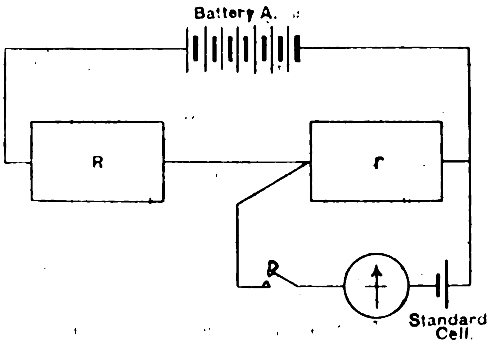

Fig. 117.

If slides or potentiometer are not available, the same test can be made by the aid of two resistances, one a fixed high resistance (R) and the other an adjustable resistance (r), connected up as in Fig. 117, where battery A is to be measured for E.M.F.

The amount of resistance required in the adjustable box (r) depends upon the amount of high resistance employed in R and the E.M.F. of the battery A. It is desirable to have some idea beforehand what approximate amount of adjustable resistance will be required to balance. This can be found by the relation

$$r = \frac{R}{\frac{E}{e} - 1},$$

where E is the approximate E.M.F. of the battery, e that of the standard cell, and R the fixed high resistance. Making R 100,000 ohms, we find that, with a standard cell of 1·43 volt and a battery of approximately 50 volts, we must provide for a range of

$$\frac{100,000}{\frac{50}{1{\cdot}43} - 1} = 2940 \text{ ohms,}$$

or not less than 3,000 ohms. If the fixed high resistance is made larger than 100,000, the range of adjustable resistance will have to be increased in about the same proportion. It would not therefore be convenient, with about 50 volts to measure, to make the high resistance more than about one-third of a megohm, in order to keep the adjustable resistance within the range of the ordinary 10,000-ohm resistance box. With higher volts however the fixed resistance could be made

Digitized by Google

greater while keeping within the range of the ordinary adjustable box.

The connections having been made as in the figure, the small resistance (r) is adjusted until there is no deflection on the galvanometer when the key is closed. The E.M.F. of the battery is then equal to

$$e\left(\frac{R}{r}+1\right) \text{ volts,}$$

where e is the E.M.F. of the standard cell. For example, say, with a standard cell of 1·43 volts, balance is obtained with 2,380 ohms in the adjustable box, the fixed resistance being 100,000 ohms. Then E.M.F. of battery is

$$1{\cdot}43\left(\frac{100{,}000}{2{,}380}+1\right)=61{\cdot}5 \text{ volts.}$$

This is identically the same as the second method given for the slides, but using resistance boxes instead of slides. The same remarks as to percentage error therefore apply, and the result to be strictly correct should be increased by the fraction $\frac{b}{R+r}$ of the whole, where b is the battery resistance.

Thus in the last example, if the battery resistance was 200 ohms, the result to be strictly accurate would have to be increased by

$$\frac{200}{102{,}380}\times 61{\cdot}5=0{\cdot}12 \text{ volt,}$$

making the E.M.F. = 61·62 instead of 61·5. The lower the battery resistance the less this correction becomes, and generally it is small enough to be neglected.

The tests for E.M.F. described are null methods, allowing of great accuracy and convenience of observation, and are readily carried out on board ship. The test by comparison of deflections through a high resistance is not so convenient on board ship nor capable of such accuracy.

The method of comparison by discharge throws is open to objection when one condenser is used for both discharges; but the throws may be made more nearly equal by using a condenser of larger capacity for the standard cell, thus increasing its throw. The E.M.F.'s are then directly proportional to the throws and inversely proportional to the capacities. This method is not a reliable one for board ship, chiefly on account of the marine galvanometer suspension being quite unsuited for reading momentary swings. Neither can the throws be read with any accuracy on a suitably suspended galvanometer with slow swing on account of the motion of the ship.

(To be continued.)

LABORATORY OF THE ELECTRICAL INSPECTOR TO THE CITY COMMISSIONERS OF SEWERS.

We publish this week a brief description of the temporary premises occupied by Mr. A. A. Voysey, the electrical inspector to the City Commission of Sewers. This laboratory is one of the first of its kind, and before proceeding to give a catalogue of its contents, it may be of interest to summarise the duties which have been placed upon the shoulders of the electrical inspector under the Electric Lighting Orders relating to the City of London. The local authority is empowered by the Orders to appoint one or more electrical inspectors, and had they failed to do so the Board of Trade would have taken the matter in hand. The duties of the electric inspector are: (*a*) the periodic inspection and testing of all the "undertakers'" electric lines and works; (*b*) the certifying and examination of meters; (*c*) such other duties in relation to the undertaking as may be required under the provisions of the Order. The fees to be taken by the inspector, the manner in which they are to be disposed, and the way in which he is to go about his work, are all prescribed by the local authority and approved of by the Board of Trade. In regard to the testing of mains the inspector has to give reasonable notice beforehand to the company concerned, and except in special cases he is not entitled to have access to the mains at any points other than those at which the company has access itself to the mains. No given section of the network may be tested more than once in three months, except in cases of emergency. In addition to the testing of mains, the electric inspector, when required to do so by a consumer, has to test "the variation of electric pressure at the consumer's terminals" and make such other tests of the apparatus on the consumer's premises as may be necessary for determining whether the company are doing their duty. The electric inspector has also to see that the testing stations, which have to be established by the electric lighting undertakers, are kept in proper order, and to examine and record the readings of the instruments set up in them. Another function of the electric inspector is the certifying of meters and the testing of the same upon consumers' premises. It will thus be seen that the electric inspector has important and multifarious functions to perform, and in the performance of them he must require no little tact and vigilance, unless he is to prove on the one hand a very thorn in the side of the company, or on the other hand a negligent guardian of the public safety and convenience.

Pending the completion of the new offices of the Commission of Sewers, Mr. Voysey has to make shift in temporary accommodation in a well-lighted room 29ft. by 23ft. in the basement of the Wool Exchange, Basinghall-street. Meter

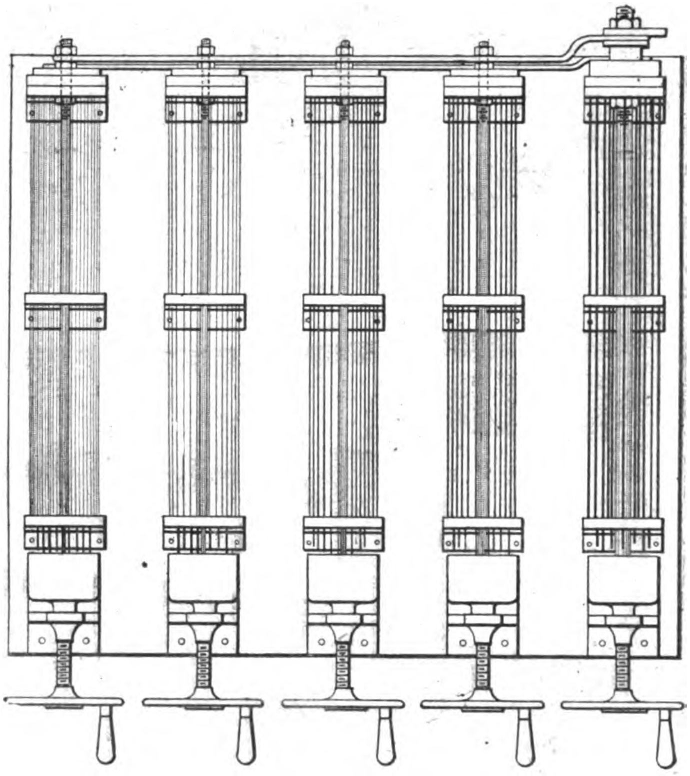

FIG. 2.—Ferranti Regulating Resistance.

testing is expected to be the chief business of the laboratory, and to that end the following arrangements have been made. Alternating current at 100 ∿ is supplied from the City of London Company's mains at 200 volts to the primary of a special 10-unit Ferranti transformer. This transformer has three secondary windings, one wound to give 100 volts and 2 amperes, another to give from 90 to 110 volts by 2-volt steps and 2 amperes, the third to give from 2 to 20 volts by by 2-volt steps and 500 amperes. The 100 and 110-volt coils are intended to supply the shunt coils of meters, and are joined in series. A 13-way commutator is provided by which the pressure of the supply to what we may call the shunt circuit can be varied from 90 volts to 110 volts by steps of 2 volts, or from 190 volts to 210 volts by similar steps. The third secondary supplies current at low pressure to a separate circuit, in which may be connected electrical quantity meters or the series coils of energy meters. A commutator which will carry the full current of 500 amperes is used, by which the pressure may be varied as required from 2 to 20 volts. The current passes from the commutator through fuses and a double-pole switch

Digitized by Google

to a copper strip extending round two sides of the room. A polished teak board, 4½in. by 1½in., supported by iron bolts fixed in the wall, carries the 1½in. by ⅓in. copper strip, the lead being screwed on the back of the teak and the return on the front. Slate shelves on solid wood corbels, placed 2ft. 6in. below the copper strip and 3ft. from the floor, carry the measuring instruments, which consist of four Kelvin balances (deci-, deka-, and hekto-ampere) and a watt balance reading up to 20 kilowatts. Two Kelvin electrostatic voltmeters are provided for the purpose of measuring pressure. A view of the voltmeters and two of the balances is given in Fig. 1. Above each balance the copper strip is cut, and the instrument connected across the break, those not in use being short-circuited by means of a copper bar and winged nut terminals. Similar breaks are provided for the insertion of meters in the circuit.

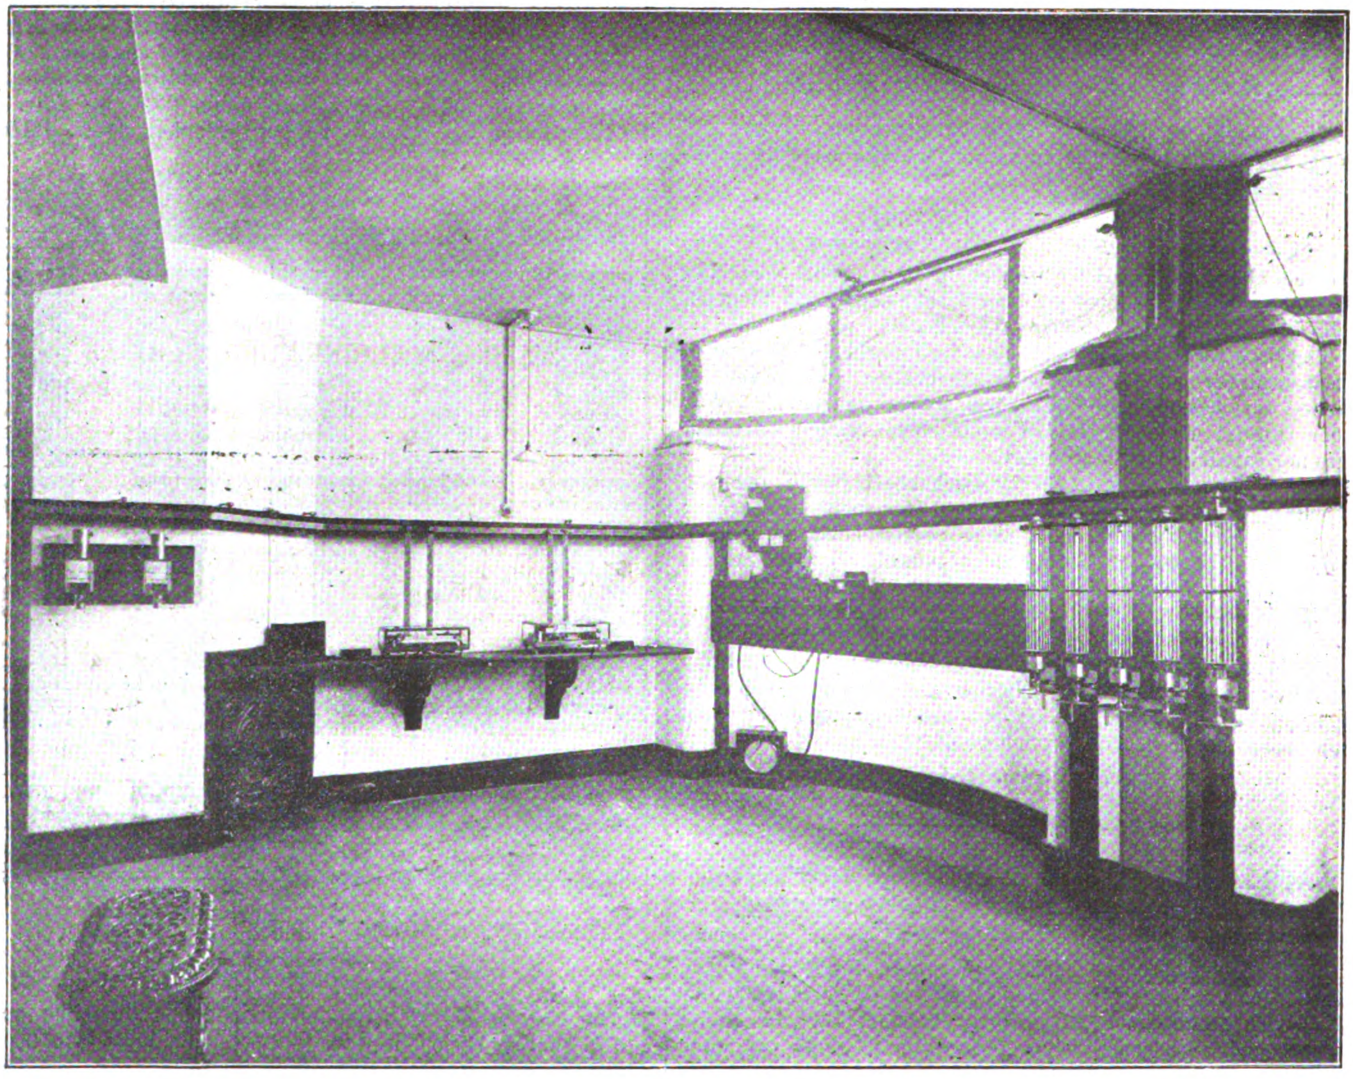

FIG. 1.—Laboratory of the Electrical Inspector to the City Commissioners of Sewers.

The current supplied to the meter circuit passes through a Ferranti non-inductive resistance, by which it can be regulated by tenths of an ampere up to 500 amperes. This regulating resistance (Fig. 2) is a particularly neat and compact piece of apparatus, and is similar in principle to that made by the same firm for the purpose of meter testing at Portsmouth. Five vertical copper rods connected together at the top by a copper bar are surrounded concentrically by German silver wires of different lengths, which are also connected together at the top, but insulated from the copper bars. Below each set of wires is a mercury cup, which can be raised or lowered by a hand-wheel actuating a screw. As the cup is screwed up the ends of the German silver wires dip successively into the mercury, which puts them in parallel and connects them in series with the copper bar, which carries the current down into the mercury cup. The first set of resistances consists of 10 wires, each carrying one-tenth of an ampere, or a total of 1 ampere; the second consists of 9 wires, each carrying 1 ampere, or a total of 9 amperes; the third of 7 wires, each carrying 10 amperes, or a total of 70 amperes; the fourth of 7 wires, each carrying 20 amperes, or a total of 140 amperes; and the fifth of 7 wires, each carrying 50 amperes, or a total of 350 amperes. Therefore, when the five cups are all in their highest position, the resistance will carry 570 amperes. It would be quite easy, if required, to provide the observer at any one of the balances with a means of regulating the resistance, by cords passing from the handwheels on the mercury cups round the room.

For the purposes of measuring conductor and insulation resistances, comparing capacities and potential differences, a Kelvin reflecting galvanometer and testing table is provided The galvanometer has separate high and low-resistance coils, and is placed with a Jacob transparent scale and stand on brackets let into a solid brick pillar. This pillar is part of the building, but looks as if it had been specially designed to carry a galvanometer. Opposite it is the testing table, with a sloping top of polished teak, on which are fixed a 4-dial pattern Wheatstone bridge, a standard ¼ megohm, a 0·3 microfarad standard condenser, and two Carhart Clark standard cells with galvanometer shunts, reversing keys, short-circuit plugs and all the usual testing-room paraphernalia. The connections are so arranged that the alteration in the position of two plugs effects the change from the Wheatstone-bridge connections to the connections for the direct deflection test for insulation or

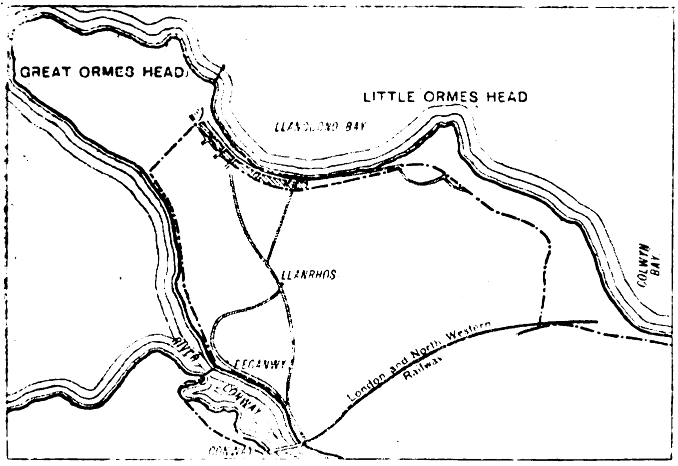
capacity. On a shelf below are 100 dry cells. The table and instruments have been supplied by Messrs. Nalder Bros., and fitted up under Mr. Voysey's direction. A standard barometer and thermometer, and the invaluable Fuller's circular rule, complete the present equipment of the laboratory.

COLWYN BAY-CONWAY ELECTRIC TRAMWAY.

The accompanying sketch map shows the route of an electric tramway which it is proposed to run from Colwyn Bay through Llandudno to Conway across the river, a distance of about 10 miles. The scheme is at present in the initial stage. The promoters have obtained the consent of the Colwyn Bay and Conway authorities, but so far have been unable to obtain the Llandudno consent. The matter was referred by the District Council to the Llandudno ratepayers, the poll resulting in an adverse majority, due principally to the strong cab interest. The promoters have taken counsel's opinion on the subject, and find that the objection of the Llandudno District Council is comparatively unimportant owing to the fact that the consents of the authorities controlling two-thirds of the route have been



Llandudno Electric Tramway.
Sketch Map showing Proposed Route. Proposed Line of Tramway shown thus —·—·—·—

obtained, and they therefore propose to proceed with the necessary plans and to apply for a Provisional Order. Nothing has as yet been decided upon as to system, but in all probability the system will be that employed on the South Staffordshire line. It will be noticed that the river Conway is crossed by the line, and to do this it is proposed either to erect a swing bridge or else to convey the tram in an electrically propelled ferry. The joint engineers are Mr. Alfred Dickenson and Mr. S. V. Clirehugh.

RECENT ADVANCES IN ELECTRO-CHEMISTRY.

In the May number of the *Journal* of the Franklin Institute will be found an interesting Paper by Mr. J. W. Richards on "Recent Advances in Electro-Chemistry," which summarises very thoroughly the various applications of this branch of science to arts and manufactures at the present time. The author points out that "to be qualified as an electro-chemist, the scientist must, first of all, be a chemist, knowing all that is implied by that term; and in addition to this, he must also be well-informed in applied and theoretical electricity"; and that to meet the demands for men with these qualifications, chairs of electro-chemistry have been established by the German universities, while in the United States, the John Hopkins University is considering the advisability of following their example. When, we wonder, will the matter be taken up in this country?

After a list of the principal societies and journals devoted to the subject follows a *résumé* of the principal applications of electro-chemistry, of which only a few can be referred to here. Though it does not appear that there is much hope that the problem of obtaining electrical energy directly from the combustion of carbon will be solved in the near future, still it is very satisfactory to learn in how many chemical industries electrical methods are supplanting those in former use. The bleaching processes, and those for the manufacture of caustic soda, are well known, but the employment of electricity for the refinement of sugar is less familiar, and it is interesting to learn that 1 E.H.P. will suffice to refine daily the syrup from 100 tons of beetroot, and that the process is in successful use in several German factories. In the manufacture of chloroform, too, the electrical method is found to be so cheap that it is superseding all others; while in the case of aniline dyes, the use of the electric current is extensive. In the manufacture of safety matches about 2,000 tons of potassium chlorate are used annually, nearly the whole of which is produced electrolytically. In the Jura Mountains there is a plant of 2,000 H.P. turning out 600 tons annually; and there is another in Dalecarlia of 6,500 H.P. But perhaps the most interesting product of the electric furnace is the calcium carbide, which has attracted so much attention of late. This was obtained by Mr. T. W. Willson, of North Carolina, in the course of experiments undertaken with the view of producing alloys of calcium and aluminium. This substance, which had been previously produced by Wöhler and others by chemical means, has, as is well known, the curious property of yielding calcium hydrate and acetylene gas on the addition of water. Acetylene has the highest illuminating power of any known hydrocarbon, and in a Paper recently read before the Society of Arts, Prof. Vivian B. Lewes made some rather sensational references to its future possibilities. An acetylene flame consuming 5 cubic ft. of gas per hour gives a light of 240 c.p.; and 1 ton of calcic carbide, yielding 11,000 cubic ft. of gas, can be made for £4. Other, and even more important uses for this gas may be found in the field of technical chemistry. For example, by passing electric sparks through a mixture of acetylene and nitrogen, hydrocyanic acid is formed, from which cyanides can be made.

AN AMERICAN ENGINEERING "UNIVERSITY."*

Purdue University at La Fayette, Ind., is the engineering school of the State, and owes its existence and support to gifts, State appropriation, and the Morrill bills, from which most of the State universities of the United States receive a considerable portion of their income. The University was established about 20 years ago. Its growth was not rapid until within the past 10 years, during which time, under the able management of President J. H. Smart, it has rapidly developed, until it stands among the leading technical colleges of the United States.

In the organisation of the University there are five distinct schools; those of civil, mechanical and electrical engineering, of science, and of agriculture; each provided with well appointed laboratories and separate faculties, but all available for the students of any one course, so far as the work of the other courses will be of advantage to the particular course considered. As this description has to do with the purely electrical work of the University, it will be confined to work done in the electrical building, a large brick structure with stone trimmings, which is given up to the uses of the department. The department of electrical engineering was established during the academic year of 1888-89 under the direction of Dr. Louis Bell, and, from a beginning with three students in that year, the department has grown until the present time, when the enrolment in electrical engineering is over 200.

The course in electrical engineering is, throughout the freshman years, almost identical with that in civil and mechanical engineering and the students have the benefit of the thoroughly appointed courses in shop work, drawing and machine design provided in the school of mechanical engineering. In the junior year, the courses begin to diverge and the work is arranged so as to include instruction in the finely-equipped mechanical laboratory, and other class and lecture work of the schools of civil and mechanical engineering, and, at the same time, make preparation for the senior work by providing instruction in the electrical laboratory, and class and lecture work on elementary electrical subjects, throughout the year. In the senior year, work in the mechanical laboratory is continued, but most of the time is spent in electrical engineering, which is arranged so as to give prominence to four distinct lines of study, as follows:–

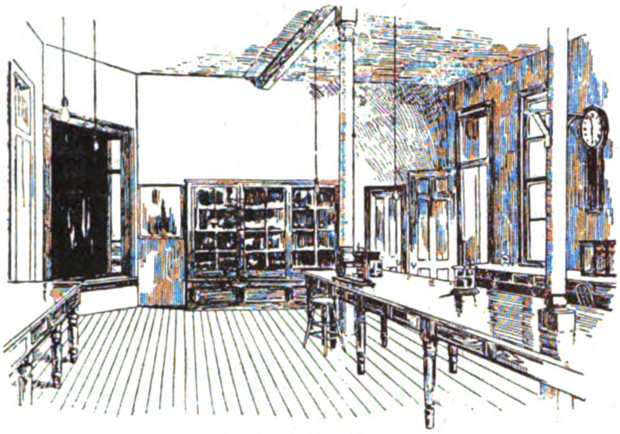
1. Experimental work in the electrical laboratory, involving the operation, testing and construction of the usual electrical machines and apparatus met with in practice; the study of direct currents incandescent, arc and power systems; of alternators, transformer, and multiphase machines; of methods of exact electrical measurement, and often the testing or installing of commercial systems under the conditions of actual engineering practice.

2. Lectures throughout the year on the general practice of electrical engineering, including the design, commercial operation and maintenance of electrical apparatus and machinery.

* Abstract from the *Electrical World* of New York.

Digitized by Google

3. Work in the drawing room in the actual calculation and design of electromagnetic mechanisms, dynamos, alternators, transformers, electrical systems of power distribution and other special applications of electricity.

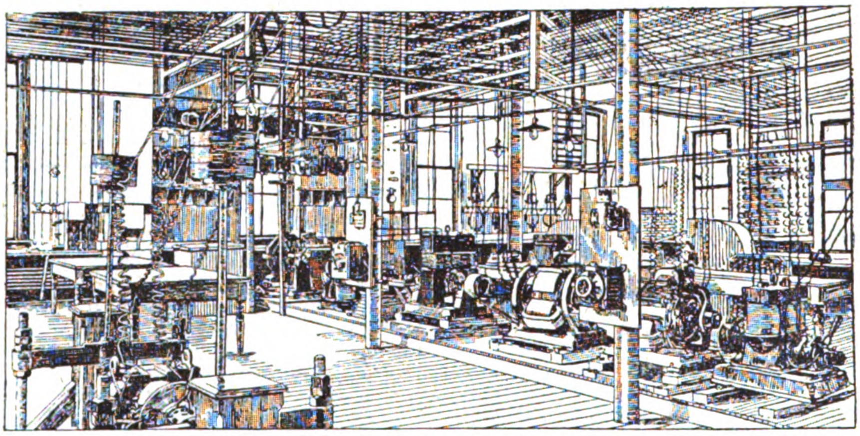


Junior Laboratory.

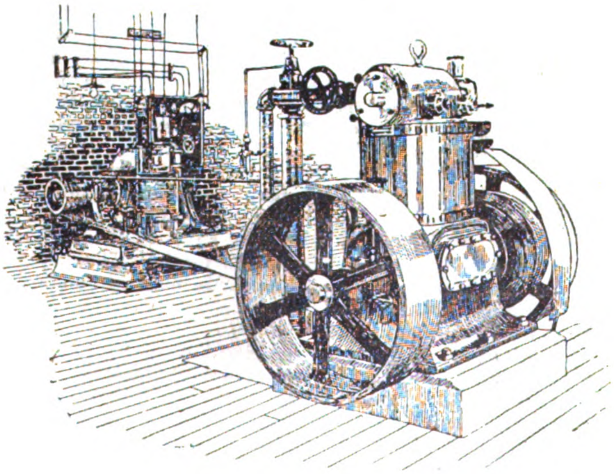
4. Lectures and recitations on the mathematical theory of electricity and magnetism.

In addition to the above, the preparation of a well-developed thesis and a trip of inspection to various electrical centres of industry is considered a part of the year's work.

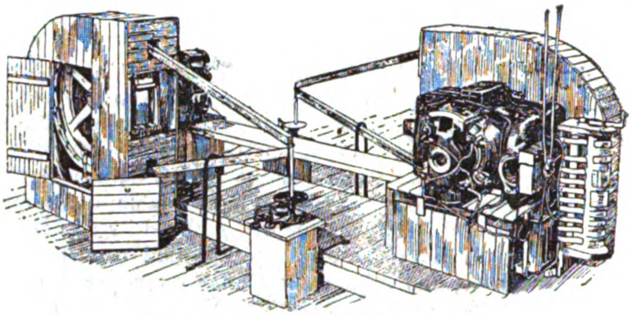
From the general view of the dynamo laboratory, it will be seen that all the larger machines are mounted on two heavy foundations extending the entire length of the room, and run from a jack shaft below the floor, each machine being provided with a friction clutch operated from the centre of the room. The jack shaft is driven by a motor with differential winding for constant speed and taking current from a 500-volt generator driven by an engine in the mechanical laboratory. This motor is provided with a tachometer and ammeter, so that the exact condition of working of the entire laboratory can be readily ascertained. This method of driving the laboratory has, for the year that it has been in operation, proved itself to be exceptionally convenient and makes possible much work that could not otherwise be performed. The aggregate power of the machines, dynamos and motors connected with the work of this room is over 200 H.P.



General View of Dynamo Laboratory.

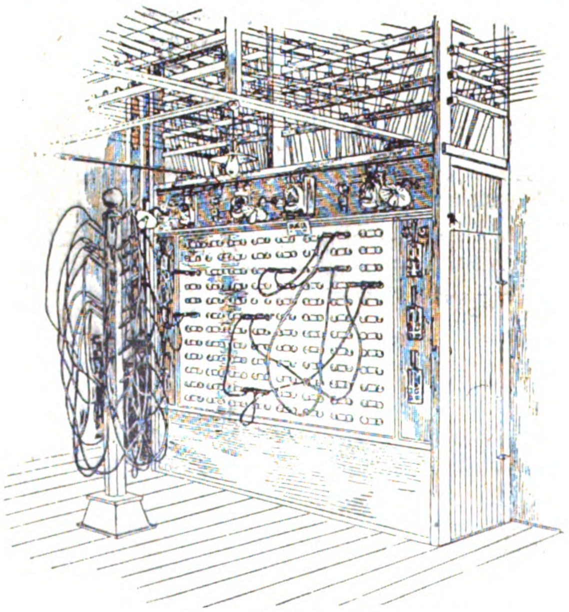


500-volt Generator and Engine.



Mounting of Street Railway Motors.

A set of German silver resistance coils are so arranged that any required resistance from 0·08 to 1,250 ohms can be readily obtained, and of sufficient capacity so that dynamo currents may be carried as high as 500 amperes for the lower resistances. For higher resistances a lamp board on which each lamp is provided with separate terminals gives a range in available resistance, for dynamo work, of any value from 1 to 40,000 ohms.



General Switchboard.

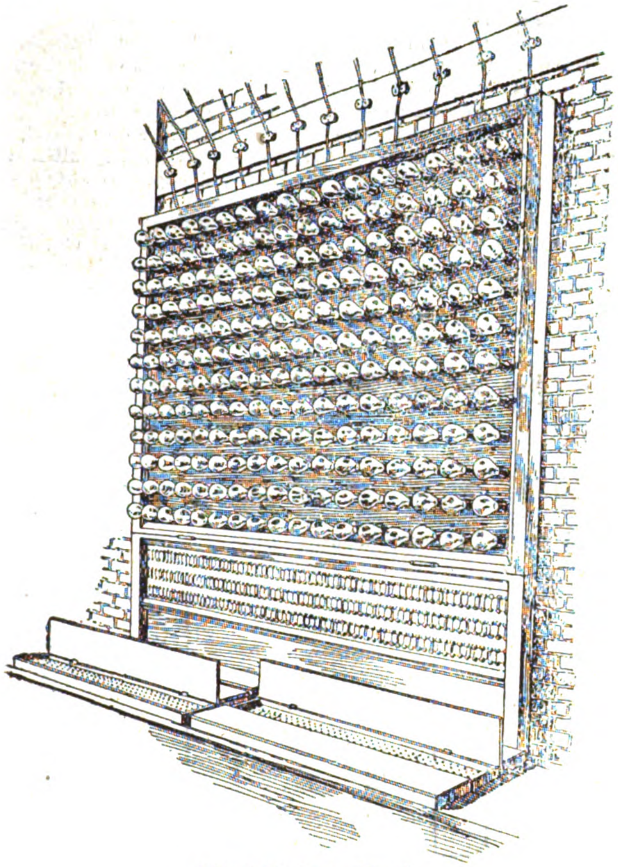
For alternate current working, there are alternators and multiphase machines and transformers of nearly every make.

There are five street railway motors of different types, two of which are shown mounted for regular class work in the laboratory,

Digitized by Google

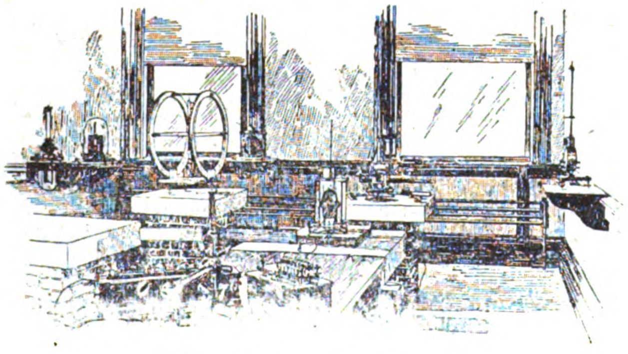
and on which a considerable amount of interesting data has been obtained.

All dynamos, motors, instruments, or other pieces of apparatus throughout the building can be connected to the general switch-board in the dynamo room, so that it is possible to secure at that point any combination of machinery, instruments and apparatus that may be desired for any piece of experimental work undertaken.



Adjustable Lamp Board.

The instruments include Kelvin electrostatic electrometers and voltmeters, Ayrton and Edelmann quadrant electrometers, 12 voltmeters of Weston and other types with multiplying coils, potential galvanometers, and other instruments. For current measurement are included two Kelvin balances, ten ammeters of Weston and



Pier Room No. 4.

other types, four Siemens electro-dynamometers, and a number of tangent, sine, Weidemann, Kelvin, D'Arsonval, Rosenthal and other galvanometers. There are also the following pieces of apparatus of importance: a Kew unifilar magnetometer, an Anthony standard resistance box, a standard subdivided microfarad condenser, an Ayrton secohmmeter and standard of self-induction, standard cells and other apparatus of less importance. The department offers a line of graduate work leading to the degree of mechanical engineer.

American Institute of Electrical Engineers.—Dr. Louis Duncan has been elected president of the Ame ican Institute of Electrical Engineers for the ensuing year.

ELECTRIC DISCHARGE THROUGH GASES.*

BY PROF. J. J. THOMSON, F.R.S.

One of the most important and interesting branches of physical science is that which deals with the connection between electrical and chemical effects. The investigations on electrolysis made within these walls by Davy and Faraday proved that the important class of electrical phenomena associated with the passage of electricity through liquids, are connected in the closest way with chemical action. They proved that no electricity will pass through most liquids unless chemical action occurs, and that for each unit of electricity which passes through the liquid there is a definite amount of chemical decomposition. This case, though it is one where the laws are most accurately known, is but one among many electrical phenomena which are inseparable from chemical action. So many instances of this kind have been discovered that we may perhaps venture to hope that we are not far from the time when it will be universally recognised that many of the most fundamental questions in chemistry and electricity are but different aspects of one and the same phenomenon. Anything which throws light on the connection between electricity and matter, interesting as it is on its own account, acquires additional interest when regarded as elucidating the connection between chemical and electrical effects, and no phenomena seem more suitable for this purpose than those which are the subject of the discourse this evening—the discharge of electricity through gases. For in gases we have matter in the state in which its properties have been most carefully studied, while the investigation of the electrical effects is facilitated by the visibility of the discharge, affording us ocular, and not merely circumstantial, evidence of what is taking place. The points to which I wish to refer particularly this evening are, firstly, some phenomena connected with the passage of electricity from the gas to the electrode, or from the electrode to the gas; and, secondly, some of the properties of the discharge when its course lies entirely in the gas.

By taking a long discharge tube, say, one 50ft. long, and observing the luminous discharge through a rotating mirror, we can trace the course of the luminosity due to a single discharge, say, one due to once breaking the primary circuit of an induction coil; if we do so, we find that the luminosity follows the direction of the positive current through the tube. That is, the luminosity begins at the positive electrode; it then rushes down the tube with enormous velocity; but when it gets to the negative electrode, it receives a check; it does not disappear at once in that electrode like a rabbit going down a hole; but lingers around the electrode some time before entering it. In consequence of this delay in the positive discharge in getting out of the gas, there is an accumulation of positive electricity in the neighbourhood of the negative electrode until the potential fall at this electrode increases to about 200 or 300 volts. The positive electricity which accompanies the discharge thus finds considerable difficulty in getting from the gas to the metal, though, as I hope to show you later on, as long as it keeps in the gas, it meets with what we may, in consideration of the views sometimes enunciated on this subject, call a ridiculously small amount of resistance, its real difficulty is to get out of the gas.

Though this effect has long been known, it is so important that I will venture to show one or two experiments which illustrate it. The arrangement of the first experiment is shown on the screen (*see* Fig. 1), the apparatus consists of a main discharge tube, across which is fastened a diaphragm made of excessively thin platinum leaf; there is a side passage from the tube, leading from one side of the diaphragm to the other, this is connected to a barometer tube, and by raising the cistern containing the mercury I can stop up the passage by a pellet of mercury. We will first observe the discharge when the side passage is open; you see that the discharge, instead of passing across the thin piece of platinum leaf, takes the very much longer route round the side tube, so as to avoid crossing the metal. We will now raise the mercury cistern and close the side tube by a pellet of mercury; the discharge now has no alternative but to cross the metal at some part of its course, and you see that the main portion of the discharge goes back into the main tube. In another experiment the metal diaphragm is replaced by a very thin plate of mica; when the side passage is opened the discharge goes round, but when this is closed by a pellet of mercury the discharge prefers to go across the mica than through the mercury.

A second experiment, which shows the same thing, is the following: Two long electrodes are fused into a bulb (Fig. 2), so that the tip of an electrode is a considerable distance from the place where it passes through the glass. We will now send an alternating discharge through the tube, and you will see, I think, that the discharge, instead of going straight across the short distance between the ends of the electrodes, goes from the tip of one electrode to the place where the other passes through the glass,

* Friday evening discourse delivered before the Royal Institution.

Digitized by Google

thus staying as long as possible in the gas before passing into the metal. The appearance of the discharge shows that the positive electrode is at the end of the wire, the negative at the junction of the wire with the glass.

Another interesting example of the difficulty the discharge experiences in passing from gas to metal is the discovery made by Profs. Liveing and Dewar, that when the discharge passes through a gas containing a large quantity of metallic dust, the light from the discharge, when examined in the spectroscope, does not show any of the lines of the metal.

The difficulty which the positive electricity finds in passing from the gas to the electrode depends a great deal upon the nature of the gas, as well as upon that of the electrode; it is influenced by the position of the gas and the electrode relatively to one another in the electro-chemical series.

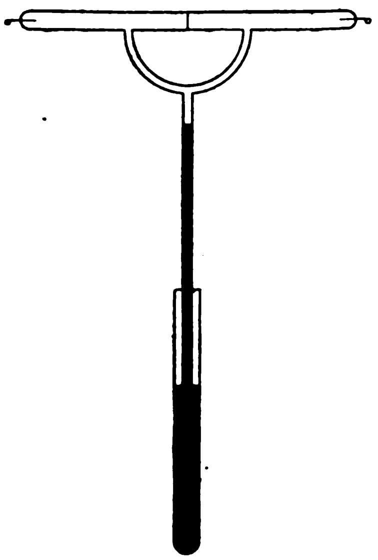


Fig. 1.

I have lately made a series of experiments on this point in the following way. An alternating discharge from a high-tension transformer was made to pass between two electrodes fused into a bulb, which could be filled with the gases under examination. Another electrode, connected to an electrometer, passed into the bulb, and was arranged so that it could be moved about from one part of it to the other. When the electrodes were metal and the bulb was filled with the electro-negative gas oxygen, the electrode received a positive charge in whatever part of the bulb it was situated; if now the bulb was filled with hydrogen at atmospheric pressure, then in the regions remote from the arc the electrode received a positive charge, but in the immediate neighbourhood of the arc itself it received a negative charge. When the pressure was

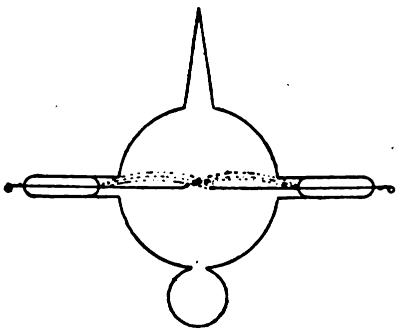

Fig. 2.

reduced, the region in which the charge was negative contracted, and finally, at pressures about one-third of an atmosphere, seemed to disappear, and the electrode got a slight positive charge in whatever position it was placed. If now, instead of using metallic electrodes, we use well-oxidised copper ones, and repeat the experiment in hydrogen, working at a pressure when there was only positive electricity when the electrodes were bright and polished, we find that with the oxidised electrodes every particle of positive electricity is taken out of the tube, and a negative charge is left. This negative charge remains until the copper oxide is completely reduced; when this occurs, the negative charge disappears, and is replaced by positive. Thus, under the same conditions as to the nature of the gas and the pressure, the bright copper electrodes leave a positive charge in the gas, while the oxidised ones leave a negative charge.

The most probable explanation of these results seems to me to be the view that the communication of electricity from gas to the electrode, or from the electrode to gas, is facilitated by the temporary formation of something of the nature of a chemical compound between the gas and the metal. In all such compounds the metal is the electro-positive element, and has the positive charge, the gas being the electro-negative, and carrying the negative charge. Now consider the case when the negative charge is on the gas, and the positive charge on the metal; then the gas and metal have got the charges proper to them in any compound they may form, and are thus in a fit state to combine, or, according to this view, allow the negative electricity to pass from the gas to the copper. But, now, suppose the gas was positively electrified, the gas and the metal have now opposite charges to those proper to them in a compound, and before the union of gas and metal in this state could result in anything but a most unstable compound, an additional process must be gone through, *i.e.*, the charges on the gas and metal must be interchanged. Thus, the conditions for the combination of the gas and metal are more complex when the gas is positively electrified than when it is negatively electrified, and thus, on the view that the communication of electricity between the gas and the metal involves a sort of chemical combination, we see that the negative electricity will escape more easily from the gas to the metal than the positive. Now consider the case when the gas was hydrogen, the electrodes oxidised copper; the hydrogen combines now not with the metal, but with the oxygen, forming water, in which hydrogen is the electro-positive element; thus, in this case, it is the positively charged hydrogen which is in the state best fitted for pairing. The consequence is the positive charge would be most readily removed from the gas and the negative leit—exactly the opposite to that which occurred when the electrodes were bright. This reversal, as I stated before, is verified by experiment.

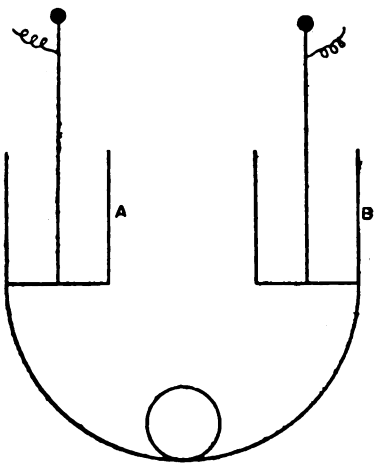

Fig. 3.

I have hitherto only spoken of the phenomena which accompany the passage of electricity from the electrode to the gas, or from the gas to the electrode. I shall now pass on to consider the properties of the discharge when it is entirely confined to the gas. We may produce a discharge which, during the whole of its course, shall be confined to the gas in the way represented in the diagram (Fig. 3). The two poles of a Wimshurst machine are connected to the insides of two jars A and B, while the outsides of these jars are connected together by a metal wire wound so as to form a coil. The electricity from the Wimshurst machine charges up the jars, the difference of potential between the poles increases until a spark passes. The passage of the spark puts the insides of the two jars in connection, and the jars are discharged. The discharge of the jar, as was proved from the theory of electro-magnet action by Lord Kelvin more than 40 years ago, and shortly afterwards confirmed by the experiments of Feddersen, is an oscillatory one, producing currents surging backwards and forwards through the wires with extraordinary rapidity. The subject of these oscillatory currents is one which in this year is tinged with melancholy. The year had hardly commenced when we lost Hertz, whose splendid work on these electrical oscillations is known to you all. The Managers of this Institution have marked their sense of the importance of this work by devoting a special lecture this session to this work alone, and they have entrusted that lecture to a most distinguished worker in the same field as Hertz. It would therefore be presumptuous on my part to refer in any detail to Hertz's work, but no physicist, and least of all one who is a member of Maxwell's University, could pass over in silence the death of Hertz. When Hertz began his magnificent experiments on electric oscillations there were many theories of electrical action. When he had finished them there was only one, Clerk Maxwell's.

Digitized by Google

Hertz's work was done with very much quicker vibrations than those produced by the apparatus now on the screen; this, however, gives rise to currents through the coil changing their direction some million times a second. If we place in the coil an exhausted bulb, the bulb in reality will be the secondary of an induction coil, and will be exposed to electromotive forces tending to produce circular currents parallel to the plane of the coil. I will now place a bulb inside this coil, and you see that a circular ring discharge passes through it, and this discharge passes entirely in the gas. The gas in the bulb now in the coil is the vapour of silicon tetrachloride; it happens to be the bulb which gives a brighter ring than any others I possess.

If this ring discharge passes through air at different pressures, the colour of the discharge changes very considerably. The first bulb I put in was at fairly high pressure, about $\frac{1}{10}$th of a millimetre or so. I will now put in another at a lower pressure, and then one at a still lower pressure. Mr. Newall, who has been working at the spectra of these discharges, finds that at the pressure in the first bulb the spectrum is due to nitrogen; at the second stage it is due to mercury vapour; the bulb was pumped by a mercury pump, so that there is in the bulb a certain quantity of mercury vapour. The apple-green colour in the more highly exhausted bulb is due to some compound of sulphur, which has got into the bulb from the sulphuric acid used to dry the gas. Mr. Newall finds that if the ordinary discharge from a coil between electrodes is taken in such a bulb, there is no trace of this sulphur spectrum. He has also found that when the bulb is at a pressure intermediate between what I may call the mercury and the sulphur stage, when the mercury and sulphur lines are both visible, these sets of lines come from different layers, the sulphur lines coming from a layer nearer the surface than the other. If we take the discharge through a bulb containing oxygen, you see that the ring discharge is succeeded by a bright glow; at first the colour is some-

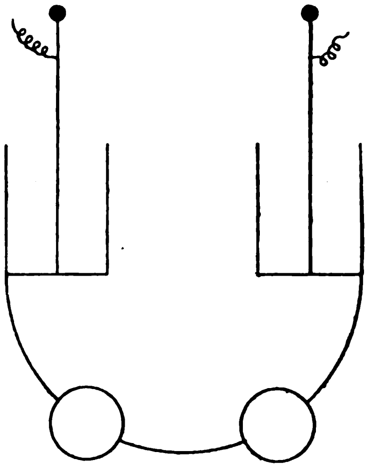

Fig. 4.

what opaque, but gradually gets more transparent and changes colour. This gives a continuous spectrum crossed by a few bright lines. If we take the discharge through cyanogen you see that the glow is even more persistent than the oxygen, though it is not so bright; all the gases which show this glow belong to the class of substances which polymerise—that is, whose molecules can combine with each other. I imagine that what takes place in bulbs filled with these substances is that the discharge produces a polymeric modification, and that this gradually returns to its original state, and while doing so gives out a phosphorescent light. It is in accordance with this that at a high temperature where ozone cannot exist a discharge through an oxygen bulb does not show any glow.

I said at the beginning of this discourse, that gases were exceedingly good conductors of electricity. I will now endeavour to show an experiment which proves that statement. The apparatus which I shall use for this purpose is a slight modification of the one I have used for producing the ring discharge; the only difference is that in the wire connecting the two coatings of the jars there are two loops instead of one (*see* Fig. 4). In one of these loops an exhausted bulb is placed to serve as a kind of galvanometer; the brightness of the discharge is an indication of the strength of the current flowing round the coil. If I place a second conductor in the other loop, currents will be started in it and part of the energy of the discharge will be absorbed; this will leave less energy available for the bulb in the first, so that the discharge in this bulb will be dimmer. The effect produced on the discharge will depend upon the conductivity of the substance placed in the second loop. The effect is not directly proportional to the conductivity; in fact, a perfect conductor would not produce any diminution, nor would an absolute non-conductor; for a given period and with apparatus of given dimensions, there is a certain conductivity which gives a maximum effect; this follows easily from the theory of induction of currents, but at this late period in the evening I will take a shorter course and prove it by an experiment.

I put a piece of brass in this loop, and you see it produces but a small effect upon the brightness of the discharge. Instead of brass I now insert a plumbago crucible, which, though a conductor, is not nearly so good a one as the brass, and you see the discharge in the indicating bulb is completely stopped. I will now place in the second loop an exhausted bulb; you see it produces a decided diminution in the intensity of the discharge in the galvanometer bulb. I now replace the bulb by another of the same size containing dilute sulphuric acid; you see it does not produce nearly so large an effect as the exhausted bulb; this might be due, as we have seen, to the sulphuric acid being either too good or too bad a

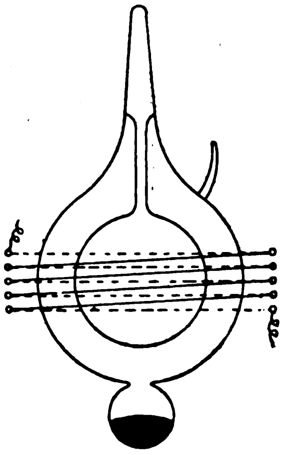

Fig. 5.

conductor. I can show that it is the latter by putting a bulb in filled with a stronger solution, which has a higher conductivity than the weak solution; if the smallness of the effect produced by the weak acid were due to its being a better conductor than the gas, then increasing the conductivity would still further diminish the effect of the acid, you see, on the contrary, that the strong acid produces a distinctly greater effect than the weak, hence the rarefied gas in the bulb is a better conductor even than the strong electrolyte.

Let us consider for a moment the molecular conductivities of the two substances, the rarefied gas and electrolyte. The pressure of the gas is about $\frac{1}{100}$th of a millimetre, while in the electrolyte there are sufficient molecules of the acid to produce, if they were in the gaseous state, a pressure of more than 100 atmospheres; thus the

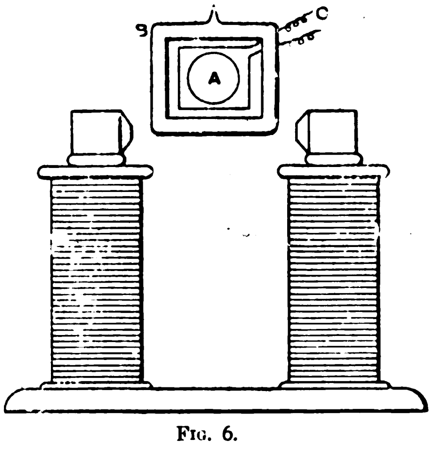

Fig. 6.

conductivity of the gas estimated per molecule is about 10 million times that of the acid; this is greater than the molecular conductivity of even the best conducting metals.

If the pressure of the gas is diminished below a certain point, the conductivity begins to diminish. I have here an experiment which I hope will show this. The apparatus (Fig. 5) consists of two bulbs, one outside the other; the inner bulb contains air at a low pressure, while the space between the two bulbs is a very high vacuum containing practically nothing but a little mercury and its vapour. The amount of mercury vapour in this space is, at the temperature of the room, exceedingly small, but as the apparatus is heated the vapour pressure increases, and we are thus able to produce a fairly wide range of pressure in the space between the

Digitized by Google

bulbs. The outer sphere is surrounded by the coil connecting the outer coatings of the two Leyden jars. When the space between the bulbs is a conductor, the alternating currents circulating in the coil will induce in this conductor currents whose inductive effect is opposite to that of the currents in the coil; and in this case this layer will screen off from the inner bulb the electromotive force due to the alternating currents in the coil. If, on the other hand, the space between the bulbs is a non-conductor, the inner bulb will be exposed to the full effect of these forces. We now try the experiment: you observe that when the mercury is cold, and consequently the pressure in the space between the bulbs very low, a bright discharge passes through the inner bulb, while the space between the bulbs remains quite dark; when we heat the mercury so as to increase the pressure of its vapour, a bright discharge passes through the outer layer, while the inner bulb is quite dark; the outer layer is now a conductor, and by its action screens off from the inner bulb the induction of the coil.

The last experiment I have to show is one on the effect produced by a magnetic field on the discharge. When the discharge has to flow across the lines of magnetic force, the pressure of the magnetic field retards the discharge; when, however, the discharge flows along the lines of magnetic force, the discharge is helped by the magnetic field. This is shown in the following experiment. A (Fig. 6) is a bulb; B a square tube, one side of which is placed between the poles of an electromagnet; the coil C, which connects the outside coatings of the jars, can be adjusted so that when the magnet is "off," the discharge passes through the bulb, but not round the square tube; when, however, the magnet is "on," the discharge passes in the square tube but not in the bulb. In the square tube the discharge passes along the lines of magnetic force, and is helped; in the bulb it passes across them and is retarded.

AN AMERICAN COMBINED WATER AND STEAM POWER STATION.*

Logansport, Ind., the county seat of Cass County, is a thriving city of about 16,000 inhabitants, situated at the junction of the Eel and Wabash rivers. Up to last December the city was paying a local lighting company $10,000 per annum for 100 street lights of 2,000 c.p., operated upon the moonlight schedule. The question of the city owning and operating its own plant had been discussed for the past five years, but it was not until the summer of 1893 that the matter began to take definite shape, with the result that last December the city's plant was started, and as far as can be judged within the short time that it has been in operation, bids fair to prove a profitable venture on the part of the city.

The city owning the water power which had been furnishing the power for the city water works for years, that power naturally suggested itself as the most desirable, principally on account of the low cost. Just before the Eel river enters the Wabash, the former has a natural fall of about 6ft., with a width of about 400ft. A 6ft. dam increases the maximum fall to 12ft., but it is only during about five months of the year that the maximum power is available, during the dry season the head often falling as low as 8ft. It was therefore decided to build a combined water and steam-power plant, both of equal capacity, so that the plant could be operated, if necessary, entirely by steam.

The station building is a substantial brick structure, T-shaped, the dynamo and engine room being 72ft. by 96ft., and the boiler room 40ft. by 80ft. The entire floor space of the main building is taken up by the turbines, electrical apparatus and engines, with the exception of a corner 24ft. by 30ft., which is partitioned off and serves as a store room and office. Above the stone foundation walls, 12in. brick walls with 18 by 24 pilasters are carried to a height of 20ft. to the roof, which is supported by 12 wooden trusses having a 72ft. span. A wire tower 8ft. by 12ft., 10ft. high, is located in the centre of the roof, and is large enough to receive the several circuits without crowding. In the centre of the boiler room a brick stack, 6ft. by 6ft. inside, and rising with a slight taper to a height of 90ft., is ample to accommodate the present and future boiler capacity.

The head race runs along the south side of the building, and before it could be made available had to be deepened at an expense of £800. The water enters the flume through an iron rack and head gates, set about 15ft. from the building, the distance being bridged over so as to give easy access to the building. The water wheel flume is 30ft. wide and 112ft. long, extending the full length of the building under the west side. The wheel pit is all blasted out of solid limestone, and walled up to the main floor, the distance from bottom of wheel pit to main floor being 21ft. The floor in the flume is 8ft. above the bottom of the wheel pit. The floors are supported on steel I-beams, supported by iron columns.

The turbines are located along the west side of the dynamo room, and are all of the Improved Little Giant type. The equipment at present consists of four of their newly-designed improved cylinder gate wheels; two 48in. turbines, rated at 130 H.P. each, at 84 revolutions, and three 36in., giving 70 H.P. each at 112 revolutions, an average head of 10ft. being assumed in each case. Each turbine is geared to its line shaft in the ratio of 1 to 4. Standard ring-oiling, ball and socket bearings are employed. Each wheel is also fitted with a Woodward water-wheel governor.

The electrical equipment consists of two 1,250-light "Standard" alternators and three 60-light 2,000-c.p. "Standard" arc dynamos, all furnished and erected by the Standard Electric Company of Chicago, who, by the way, were the general contractors for the entire plant, with the exception of the site and building, which were furnished by the city. The dynamos are symmetrically arranged along the centre line of the dynamo room, the alternators being belted to the larger turbines, while each of the smaller wheels serves to drive one of the arc dynamos. From the generators all wires are led under the floor to a three-panel marble switchboard fitted with all necessary appliances in the way of current and pressure indicators, switches, ground detectors, rheostats, &c. From the switchboard overhead conductors lead out to the wire tower, where each circuit is provided with lightning arresters before leaving the building.

Along the east side of the dynamo room are four centre crank automatic engines, having a combined capacity of 440 H.P. Three of the engines have 13in. by 12in. cylinders, giving 65 H.P. All of the engines are speeded to 300 revolutions and take steam at a pressure 110lb. The engines are placed at such a distance from the dynamo that in changing from water to steam power, or *vice versâ*, it is merely necessary to shift the dynamo belt from one to the other, proper allowance having been made for the difference in diameters between engine and turbine pulleys. It is, of course, desirable that in either case the "pulling" portion of the belt be next to the floor; this necessitates reversing each dynamo in changing over, which is probably the only objection that could be urged against the arrangement, and is fully offset by its flexibility.

In the boiler room are five horizontal tubular boilers, 60in. by 16ft. each, a 500 H.P. feed water heater and two boiler feed pumps, either pump being large enough to feed all the boilers at a piston speed of about 24ft. per minute. The boilers are fitted with gas burners, natural gas being piped to the plant, but at present the city is burning coal, Indiana block coal being delivered to the station at $1.25 per ton. With gas furnished at 7½ cents per 1,000ft., it has been found that coal is slightly cheaper. The engine and boiler equipment was furnished by the Erie City Iron Works, and at the test made by the city's consulting engineer, proved not only fully up to the guarantees made by the contractors, but in some respects even better results were obtained than were anticipated.

The outdoor wiring consists at present of one incandescent and three arc circuits, the latter containing 34 miles of No. 6 weather-proof wire. For the incandescent circuit a No. 00 feeder is run a distance of half a mile to a centre of distribution, from which the lights are distributed through about 10 miles of mains and branches.

It was stated at the beginning of this article that the plant is looked upon as a paying investment by the city. The total capacity of the plant, as constructed at present, will furnish 180 2,000-c.p. arc lights and 2,500 16-c.p. incandescents. The entire cost to the city in round numbers will be £12,000. One hundred and fifty of the arc lights will be used for street lighting, and will, therefore, bring no direct revenue to the city. The remaining 30 arcs the city will rent as commercial lights at $6 per month, giving an income of at least $2,000 per year. Of the 2,500 incandescent lights, it is expected that 1,500 will be disposed of as commercial lights and 1,000 for residences, the income at meter rates, 7 cents per kilowatt-hour, being estimated at $14,000 per year, making a total of $16,000.

In estimating the operating expenses, which are given at $10,000 per year, it must be borne in mind that during five months of the year (February to June) the entire plant can be operated by water power, which, as stated, costs the city nothing. Part of June and July one-half steam and one-half water will be used; July, August, and September all steam, and from that till January half steam.

In the $10,000 are included cost of coal, salaries ($600 per month), oil, carbons, incidentals and depreciation at 5 per cent. The management of the plant is under the direction of a council committee, appointed for that purpose. The salaried positions consist of one superintendent and electrician, one assistant electrician (dynamo tender), one engineer, one fireman and two trimmers.

Inside wiring for incandescent lighting is paid for by consumers, the city doing the work at a trifle above cost. Lamp renewals are paid for by consumers, the city selling 16-c.p. lamps at present at 30 cents.

Another source of revenue which the city has in contemplation is the establishment of a power service during the day, the conditions being exceptionally favourable for this, on account of the

* Abstract of an article by C. Kammeyer, in the *Electrical Engineer* of New York.

Digitized by Google

ease with which the combined power and lighting load, so troublesome in ordinary stations in the early evening hours, especially on dark winter days, can be taken care of in a plant such as described above.

THE ELECTRICAL MEASUREMENT OF STARLIGHT.*

BY G. M. MINCHIN.

The method employed in these experiments for measuring the intensity of the light which reaches the earth from the stars and planets consists in the determination of the E.M.F. generated by such light in certain photo-electric cells, the square of this E.M.F. being proportional to the energy of the incident light.

In these cells the surface on which the incident light is received is formed by depositing a thin layer of selenium on a surface of clean aluminium, and immersing the sensitive layer in a glass cell filled with œnanthol.

The seat of the E.M.F. is the surface of contact of the liquid and the selenium, the selenium receiving a positive and the liquid a negative charge.

An examination of a seleno-aluminium cell with the various portions of the spectrum of lime-light shows that the cell is sensitive to all the rays from the end of the red, and below it, to beyond the violet, the maximum E.M.F. being produced in the yellow; but the magnitude of the E.M.F. does not vary very greatly until the violet is reached. In this respect the seleno-aluminium cell differs from all other photo-electric cells, for the sensitiveness of most of the latter is almost wholly confined to the blue. It may be mentioned, however, that a cell formed by immersing clean silver plates in a solution of eosine gives electromotive forces of opposite signs for the red and the blue rays.

The energy incident on a photo-electric cell has been found to be proportional to the square of the electromotive force generated. If one candle held at a certain distance from the cell gives a difference, E, of potential between the poles, two candles close together will be found to give a difference $E\sqrt{2}$. Or, if a candle be tried at different distances from the cell, the difference of potential will be found to vary inversely as the distance.

If I is the total amount of energy radiated into space in any time by a star at the distance r from the earth, the quantity received on any given surface on the earth will be proportional to I/r^2; and if E is the E.M.F. which this generates in a given cell, we have

$$I/r^2 = kE^2 \quad \ldots\ldots\ldots \quad (1)$$

where k is some constant. Hence, if I′ is the intrinsic energy of another star at the distance r', and E′ the corresponding E.M.F.,

$$I'/r'^2 = kE'^2, \quad \ldots\ldots\ldots \quad (2)$$

from which we have

$$\frac{I}{I'} = \frac{E^2 r^2}{E'^2 r'^2}. \quad \ldots\ldots\ldots \quad (3)$$

Hence, if the parallaxes of the two stars are known, say p and p' respectively, we have

$$\frac{I}{I'} = \left(\frac{Ep'}{E'p}\right)^2. \quad \ldots\ldots\ldots \quad (4)$$

When it is desired to compare the energy of a star with that of the sun, we must know the area of the sensitive layer of selenium in the cell. Let this be a, and let A be the area of the aperture of the telescope.

Then, since it is not desirable to concentrate on the selenium the amount of solar light which falls on the large area A, we must turn the cell to the sun without the aid of the telescope. Let E be the E.M.F. observed, S the intrinsic energy of the sun, and r the distance of the sun from the earth. Then

$$a\frac{S}{r^2} = kE^2, \quad \ldots\ldots\ldots \quad (5)$$

while, for any star whose distance is R, giving an E.M.F. equal to e,

$$A\frac{I}{R^2} = ke^2. \quad \ldots\ldots\ldots \quad (6)$$

$$\therefore \frac{I}{S} = \frac{a}{A}\left(\frac{eR}{Er}\right)^2. \quad \ldots\ldots\ldots \quad (7)$$

As the E.M.F. produced by the light of the sun falling directly on the cell is probably too large, it will be desirable to diminish its intensity by taking it through a small measured aperture and placing the cell at a known distance behind.

The instrument employed for measuring the E.M.F.'s generated by the light of different stars is a quadrant electrometer differing from the forms in ordinary use in having its quadrants made of aluminium, two of these being supported on brass pillars connected with the case of the electrometer and always earthed, while the other two are supported on pillars of melted quartz.

It had been intended to use with the electrometer an air condenser consisting chiefly of two gilt brass plates, each about 15cm. in diameter, to multiply the potentials indicated by the electrometer; but at present there are difficulties in the way of its employment, and the measures made on this occasion were made by the electrometer alone. Both instruments were constructed with the aid of the Government grant dispensed by a Committee of the Royal Society and were made by Mr. Paul, of Hatton Garden.

The telescope was Mr. Wilson's 2ft. reflector, which was at first used as a Cassegrain instrument, and subsequently as a Newtonian, the cell-carrier being in each case fixed to the telescope in place of the eye-piece.

One pole (the insensitive) of the cell was connected with earth by a wire attached to a gas pipe, while the other (that of the sensitive surface) was attached to a fine uncovered copper wire, carefully insulated throughout, which passed down through a shellac plug in the floor of the observation room to the electrometer in the room below.

The readings of the electrometer deflections caused by the light of the stars were made in the lower room by Prof. Fitzgerald, while Mr. Wilson and I attended to matters upstairs. But in this part of the work the services of my two colleagues were of very much greater use than mine.

Regulus was the first star taken, and only two observations of the deflection on the electrometer scale produced by its light were made before proceeding to an examination of Arcturus for comparison. It is thought desirable to show in tabular form a few of the results obtained. A Leclanché cell produced on the scale a deflection of 530mm., the scale being about 7ft. from the electrometer.

Experiment.	Scale reading, star off cell.	Scale reading, star on cell.	Scale reading, star off cell.	Difference from mean.
1	150	146·5	151	4·0
2	151	146·0	150	4·5

Every photo-electric cell of the type previously described, and of maximum sensitiveness, has a certain native or disturbing E.M.F., which is always opposed to the E.M.F. generated by light. In this case it was represented by 11·2mm. The second column of this table contains the number on the scale at which the spot stood when the cell was in the dark, *i.e.*, when the only E.M.F. in it was its disturbing E.M.F.; the second column contains the number to which the spot moved when the light of the star was allowed to fall on the sensitive surface in the cell. It will thus be seen that the E.M.F. due to Regulus in these two experiments was represented by the number 4·25, or about 4·25/530 of a Leclanché.

Arcturus when tried gave the following results, after a few preliminary observations (which were tried in the case of Regulus also, and which are rendered necessary after the disturbances caused in shifting the telescope, &c.):—

Experiment.	Reading, star off.	Reading, star on.	Reading, star off.	Difference from mean.
1	135·5	128·0	135·5	7·5
2	135·5	Clouds	came	up.
3	145·0	138·0	143	6·0
4	143·0	Clouds	came	up.
5	136·0	137·0	Found star	off the wires.
6	189·0	132·5	139	6·5
7	139·0	130·0	135	7·0
8	135·0	127·0	134	7·5

These observations were somewhat irregular, because the sky was not quite clear during most of the observations, but was getting clearer as they proceeded.

The last was probably the best observation, and in that case Arcturus produced a voltage of about 0·02.

An experiment was made to try whether, if the cell were exposed to the sky in the neighbourhood of the star, but not to the star itself, any effect was produced, and a deflection of about 0·5mm. in the direction *opposed* to that of the deflection caused by light was constantly observed.

If we take this effect into account, we have as the deflections due to

Regulus .... 4·75
Arcturus .... 8·00

Assuming now the latest determinations of the parallaxes of these stars to be

Regulus .... 0·093″
Arcturus .... 0·018″

* Observations made at the Observatory of Daramona House, co. Westmeath, in April, 1895. Abstract of Preliminary Report, read before the Royal Society.

Digitized by Google

we have from equation (4) the ratio of their respective intrinsic energies, I, I′, the result

$$I'/I = 75{\cdot}72,$$

showing that Arcturus radiates into space about 75¾ times as much energy as Regulus in a given time.

The telescope was next turned to the star η Bootis. If the radiation to the sky is added, the star's deflection amounts to 1mm., *i.e.*, a voltage of 0·0028. This observation is, however, recorded merely for the purpose of showing that a comparatively faint star is able to give an unmistakable E.M.F.

The telescope was next turned on Saturn, whose image was so large that the ends of his rings were probably off the sensitive surface in the cell. The observation was :—

Experiment.	Reading, star off.	Reading, star on.	Reading, star off.	Difference from mean.
1	129	125·5	129	3·5
2	129	125·0	129	4·0
3	129	122·5	126	3·75

Between the second and third of these experiments the cell had been slightly disturbed, so that the last is not very satisfactory, although it gives the mean result. The glare from the moon was now very distinctly apparent, and its effect seemed to be a deflection of about 0·5mm., which must be deducted from Saturn's effect. This latter would, then, be represented by about 3·25mm., or a voltage of 0·009.

Comparison with the Photometric Method.—In the ordinary method of comparison of "magnitudes," if B and B′ are the brightnesses of two stars whose magnitudes are *m* and *m′*, respectively, we have, by definition,

$$\log \frac{B}{B'} = \tfrac{4}{10}(m' - m). \quad . \quad . \quad . \quad . \quad . \quad (5)$$

Now, taking Arcturus and Regulus as of the magnitudes 0·3 and *m′*, respectively, and the E.M.F.'s of their lights as 8 and 4·75 (determination of April 11th, previously cited), we have

$$\log \left(\frac{8}{4{\cdot}75}\right)^2 = \tfrac{4}{10}(m' - 0{\cdot}3),$$

$$\therefore m' = 1{\cdot}43.$$

The magnitude of Regulus, as a matter of fact, is variously cited as from 1·42 to 1·7 ; thus the amount of correspondence between the photo-electric and photometric methods is seen.

Concluding Remarks.—It is hoped that these measurements will be resumed about the end of next September, at Daramona, by the same obervers ; and, in the meantime, some improvements will be effected in the cell-holder which will facilitate observation. An endeavour will also be made to improve the cell itself in the directions indicated at the beginning of this report.

The experiments prove conclusively that there is little difficulty in obtaining fairly accurate measurements of the light of stars of the first and second "magnitudes," even without the employment of a multiplying condenser or a larger telescope. A telescope with an aperture of 5ft. or 6ft. would certainly annex a very great number of stars to the list.

It is right to put on record the fact that the first photo-electric observations of planets and stars were made by Mr. Monck, in Dublin, in the year 1892, in conjunction with Prof. Fitzgerald. My cells were at that time much less sensitive that the present ones ; and, for reasons set forth in this Paper, their sensitiveness fell off after about six hours. The liquid in those cells was acetone, and the aluminium on which the selenium was deposited was not insulated from the liquid. Nevertheless, Mr. Monck and Prof. Fitzgerald were able to observe electromotive forces due to the light of Venus, Jupiter, and, I think, Mars. Mr. Monck's telescope is a refractor of 9in. aperture, so that large results were not to be expected. These observers were not quite certain whether Vega and Capella produced measurable effects or not ; but their observations were much interfered with by draught of air, and other things, in their observatory.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May 25, 1895.*

Electric Railway Litigation.—After some years of preparation the suit involving the street railway trolley is about to be brought to a hearing. This appears to be another of the causes from which only the lawyers will derive profit, which, by the way, seems to be characteristic of electric street railway suits, none of the "broad" patents relating to this branch having thus far been sustained. In the present instance the defence is based upon prior invention, and numerous patents are cited granted for trolleys for use with systems for telegraphing to and from moving trains. Shortly after the introduction of the practical telegraph, the problem of train telegraphy became a favourite one with inventors, and during the 20 years previous to 1870, numerous patents were issued on this subject involving the use of the trolley. Many forms of the latter were invented, including over-running, under-running, and lateral trolleys, applied to overhead wires, side wires and underneath rail conductors. The question at issue would, therefore, seem to be whether a trolley transmitting a large current to an electric motor is a different invention from a trolley transmitting a small current to a telegraph instrument, and a well-established principle in patent law indicates the probability of an answer in the negative.

The Berliner Telephone Transmitter Patent.—The recent decision of a United States Court of Appeals, reversing Judge Carpenter's decision nullifying the Berliner microphone patent, was a great surprise, and has spread consternation in telephone circles. It had been taken for granted that there was no probability of a reversal, and several hundred telephone exchanges in competition with those of the American Telephone licences had been started in various parts of the United States, while many firms had commenced the manufacture of telephone apparatus. There were two questions involved in the appeal: the illegality of the Patent Office proceedings, which delayed the issue of the patent for 14 years, and the point whether the 1880 Berliner patent included the invention claimed in the 1891 patent. The judges hurriedly delivered their decision immediately after it had been determined in order to avoid any possibility of a "leak" that would cause stock speculation, and the opinion sustaining it will not be ready for publication for several weeks yet. In the meantime there is much interest as to the reasons assigned for the reversal, there being some hope that it will leave grounds for a more successful issue under another method of legal procedure. The litigation thus far will result in some good even should the monopoly of the Bell Company be extended to 1908, for competition during the last several months has caused that Company to grant large reductions in telephone rentals throughout the United States in the smaller cities, and any attempt to increase to former rates would be undoubtedly prevented by legislation.

The New Westinghouse Works.—The new works of the Westinghouse Company at East Pittsburgh, Pennsylvania, are now in operation, about 3,500 men being employed at present. The great manufacturing district in which the works are situated owes much of its fame and prosperity to the economy in which manufacturing operations are conducted, labour-saving processes and workshop organisation having there been brought to a remarkable state of efficiency. We may remark in this connection that Mr. Carnegie ascribes the enormous profits made by his firm to this cause rather than to the favourable situation of his works with respect to other manufacturing conditions. Mr. Westinghouse has been a recognised expert in this department of the art of manufacturing, and has had a wide field for practice in connection with the many enterprises with which he is connected—notably with respect to the immense shops of the Westinghouse Air Brake Company—and the new electric works have received the benefit of his long experience and study in its equipment and organisation. The claim made, therefore, that the new works at East Pittsburgh form the finest example in existence of an electrical manufacturing establishment is one having a reasonable basis, and those who have visited the establishment are enthusiastic in praise of what they have seen.

CORRESPONDENCE.

PRESSURE CURVES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to Mr. T. Cooper's letter on this subject in your current issue, I regret to find that, through an unfortunate error, the St. Pancras curve given in your issue for May 24th actually represents the electrical pressure variations in Fitzroy-square for the 24 hours from noon May 2nd to noon May 3rd, instead of for the complete day of May 2nd as was intended.

I have also to express my regret, having regard to what is mentioned in Mr. A. P. Trotter's letter, that the curve of the Kensington and Knightsbridge Company for March 20th was inadvertently given in place of that for March 19th.

I should at the same time like to be allowed to acknowledge my indebtedness to Messrs. Drake and Gorham—the owners of the Cardew patent under which all these voltmeters are made—for having kindly lent to me the very sensitive instrument with which all these records were taken.—Yours, &c.,

66, Victoria-street, Westminster, A. A. C. SWINTON.

VACUUM TUBE AFTER-GLOW.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In his communication on "Curious Vacuum Tube Phenomena" in *The Electrician* of May 10th, Mr. W. Lomas has broached a subject which seems to merit greater attention than it has as yet received.

Mr. Lomas will find a brief description of the phenomena referred to, as observed by Mr. H. M. Martin and myself, in the *Electrical World* (N.Y.) of January 20, 1894, and in a later issue of the same paper the method of obtaining the effect by means of a small incandescent lamp and a Ruhmkorff's coil is detailed (*see* "The After-glow in Exhausted Bulbs," the *Electrical World*, January 20, 1894, and "Tesla Effects with Simple Apparatus," the *Electrical World*, September 1, 1894).

I have in addition collected the following data, which may be of assistance to Mr. Lomas in suggesting lines for further investigation.

While the use of the Ruhmkorff's coil in producing this effect is interesting in some connections, the influence machine is better adapted to a study of the after-glow proper, and most of the results following were obtained by its aid.

If an ordinary 16 c.p. glow lamp be held in the hand by the bulb and the base brought near the collector of an influence machine, sparks will pass, the base and filament will become charged, and the interior of the bulb will glow.

If the charging be continued the filament will bend and gradually approach the side of the bulb, and when the charge is sufficiently intense, and the filament quite near the glass, the crackling discharge which Mr. Lomas mentions takes place, and the filament regains its normal position. But if the lamp be withdrawn before the discharge occurs, the after-glow is established and continues for several minutes, as Mr. Lomas describes.

Experiments were made with a bulb containing some loose pieces of carbon in addition to the sealed-in filament. This arrangement possessed great capacity, and when charged and laid upon a table at a distance from any other objects of capacity sustained the after-glow for eight minutes.

These and other experiments seem to warrant the conclusion that if a charged body be surrounded by a rarefied gas, the molecules of the gas will be attracted, and coming in contact with the body, receive charges and be thrown off. When there is but one charged body these movements will cease when the molecules have all received charges, but if there be two or more bodies with charges of different signs or intensity, molecular journeyings will go on between the bodies until equilibrium of charge has been established, the action being that exhibited by the well-known "electric chimes."

It appears, also, that a relatively small difference of electrostatic potential may give rise to molecular collisions and bombardments sufficiently energetic to produce a visible glow. Indeed, so little charge is required that the glow is often observed without apparent cause.

On two different occasions I have grasped a perfectly dead lamp in a dark room, and been astonished at seeing a glow caused by the charge excited in my body by walking across the carpeted floor; and I have frequently produced the glow in a lamp by simply rubbing the base briskly with a silk cloth.

At first sight the foregoing theory seems inadequate to account for the continued maintenance of the glow in a bulb having only a single terminal capable of taking a charge, and the possibility of stimulating and apparently controlling the glow through the glass of the bulb by rubbing with the hand, &c., but a consideration of the extreme minuteness of the individual molecular charges may afford an explanation.

The molecules and their charges must be so infinitesimal that it is reasonable to believe that they are discharged by contact with even so poor a conductor as the glass bulb, and that the proximity of the hand simply assists in the accumulation of a charge on the interior surface of the bulb, which, aided by the condensing power thus obtained, may become sufficiently intense to discharge through the thin glass, so causing the crackling sound heard by Mr. Lomas.

Probably but comparatively little energy is expended in supplying the molecular charges, the capacity required to sustain the glow for the maximum time observed (eight to ten minutes on a single charge) being necessary because of the great losses by dissipation, surface leakage, &c.

The difference between this method of obtaining vibration of the gas molecules, and that with which the name of Mr. Tesla is associated, has been pointed out.—Yours, &c,

May 27, 1895. W. H. PALMER, JR.

LEGAL INTELLIGENCE.

Bryson v. The Town Commissioners of Crieff.

An action was recently brought in the Sheriff's Court by Mr. W. A. Bryson, consulting electrical engineer of Glasgow, against the Commissioners of Crieff and others for the sum of £26. 5s. in respect of professional work alleged to have been done on the defenders' behalf in connection with the proposed introduction of electric lighting into Crieff. Having heard the evidence, the Sheriff found that the pursuer had failed to prove his employment by the defenders, either as individuals or collectively, and dismissed the action with costs against the pursuer. The Sheriff stated that in considering the pursuer's claim no question arose as regarded his having performed the work for which he charged or the fairness of the charges made. The sole question was one of employment, and with reference to this the pursuer was entitled to the benefit of the fact that the work in question was, in the first instance, undertaken by him on the suggestion of the defender Veitch, whom he had some reason to believe was acting with the knowledge and approval of the burgh authorities, and in view of the same anticipated action on their part for the introduction of electric lighting into the burgh, and that this was a matter in which the defender Adie, as Provost of the burgh, took special interest. In so far, therefore, the circumstances of the case may be held to be favourable to the pursuer, but they do not afford evidence either of actual or implied employment to perform the services he has rendered. It was clear that the Burgh Commissioners in their corporate body did not authorise his employment, nor were the communications, written or verbal, which passed between him and the defenders Adie and Veitch, such as to establish that, as acting on behalf of the Commissioners and with their authority, they employed the pursuer to perform the work in question.

Acetylene.—According to the *Gas World*, the Neuhausen Aluminium Company is making calcium carbide for 6d. a kilogramme, or £25. 7s. a ton, and holds out hopes that if there be a sufficient demand it may be able to reduce the price materially for large orders. At the present moment, it is said, that calcium carbide is being sold in London in two shillings 2lb. tins. Herr Wedding, says the same authority, has found that there is a great difference between the acetylene yield of various samples of calcium carbide. One sample, from Pintsch's, gave 64·5 litres per kilogramme; another gave 115·7; one from the Neuhausen works gave 96·8; one made by himself gave 254·3; while the theoretical is 348.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett (*now ready*). Strong portfolios can be had, price 1s. each. A full prospectus can be obtained post free.

"THE ELECTRICIAN."—A special notice concerning certain changes in the price, &c., of this journal will be found on page 190.

TENDERS INVITED.—The Electric Lighting Committee of the Corporation of St. Helens (Lancs.) invite tenders for the supply and erection of boiler and engine-house plant, switchboard and instruments, underground work (including cables, boxes, culverts, &c.), transformers and fittings, meters, and overhead crane for their electric lighting station. Specifications, plans, &c., can be obtained from Mr. Robert Hammond, the consulting engineer to the Corporation, Ormond House, Great Trinity-lane, London, E.C., after the 11th inst., and tenders are to be sent in to Mr. W. J. Jeeves, Town Clerk, Town Hall, St. Helens, not later than Tuesday, July 2nd. Some further particulars appear in our advertisement columns.

——— The Italian military authorities at Pavia are inviting tenders for the supply of 105,600 metres of rubber-covered telegraph wire 1·6mm. in diameter. Tenders must be sent to the Direz. Offic. di Construz. Mat. Genio Milit., Pavia.

——— Tenders are invited by the General Direction of the Roumanian Posts and Telegraphs at Bucharest until June 15th for the supply of 4,000 Callaud cells for telegraphic purposes."

——— The Municipal Authorities of Medina del Campo (Valladolid, Spain) are inviting tenders until the 27th inst. for the concession for the electric lighting of the town during a period of 20 years, the Municipal Authorities reserving the right to annul the concession at the end of eight years. Tenders are to be sent to the Ayuntamiento de Medina del Campo (Valladolid).

——— Tenders are invited by the Municipal Authorities of Astorga (Province of Leon, Spain) for the concession for the electric lighting of the town during a period of 20 years. Tenders are to be addressed to the Ayuntamiento de Astorga (Leon).

TENDERS ACCEPTED.—The Burton-on-Trent Town Council have accepted the tender of the Telegraph Manufacturing Company, Helsby, near Warrington, for high and low-pressure cables for their electric light extensions, and they have also accepted the tender of the Stanton Ironworks Company for cast-iron pipes.

——— The Gas, Electricity and Street Lighting Committee of the Bolton Corporation have accepted the tender of the British Insulated Wire Company for supplying and laying down the mains required for their electric lighting extensions.

——— The Electric Lighting Committe of the Brighton Town Council have received the following tenders for the 80 cast iron and drawn steel bracket posts arc lamps:—

Peirson and Co., London	£3,680
Newton, Chambers and Co., Sheffield	2,640
Hart, Son, Peard and Co, Birmingham	2,600

Informal tenders were received from Messrs. MacFarlane and Co., Messrs. Reed and Co., Messrs. G. Smith an Co., Messrs. Mackenzie Bros., Messrs. Baird, Son and Thompson, and the Alloa Iron Company. The Committee recommend that the tender of Messrs. Hart, Son, Qeard and Co. be occepted.

The tenders received for the supply of 45 cast-iron upright posts, wlth bracketed canopies, for arc lamps, need further consideration, and the Committee deferred their recommendations on these tenders till the 20th inst.

SALE BY AUCTION.—Messrs. Wheatley Kirk, Price and Goulty will sell by public auction at the Mart, Tokenhouse-yard, London, E.C., on Thursday next, June 13th, at 12:30 for 1 o'clock, the entire valuable property of the Val d'Aosta Syndicate, Limited (in liquidation), consisting of freehold works, mines, &c., with engines, boilers, plant, railways, water rights, &c., of which particulars are given in our advertisement columns. The plant is in first-class condition, and is especially suitable for carrying on the trade of copper depositing, refining, and smelting. This sale offers an exceptional opportunity for capitalists, as the works, plant and patent rights are practically sold as a going concern. The auctioneers, Messrs. Wheatley Kirk, Price and Goulty, of 49, Queen Victoria-street, London, E.C., and Albert-square, Manchester, will supply plans and descriptive particulars gratis, as will also the liquidator, Mr. F. R. Reeves, Mansion House-buildings, E.C., the solicitors, Messrs. Deacon, Gibson and Medcalf, 9, Great St. Helen's, E.C., and Messrs. Mackrell, Maton, Godlee and Quincey, 21, Cannon-street, E.C.

SALE BY AUCTION—Under an order of the High Court of Justice Mr. William Izard (Messrs. Izard and Izard), of 52, Gracechurch-street, London, E.C., will sell by auction on Tuesday, June 18th, at 12 o'clock, the valuable and extensive stock, plant, and machinery of the Ford-Lloyd Manufacturing Company (Limited) at Phœnix-place, Mount-pleasant, Clerkenwell, E.C. Some further particulars are given in our advertisement columns.

APPOINTMENT VACANT.—The Governors of the Merchant Venturers' Technical College, Bristol, invite applications for the post of junior assistant master in the boys' school, at a salary of from £100 to £120 per annum. Applications have to be in by June 22nd. Our advertisement columns contain some further particulars.

——— A gas and electricity manager is required by a gas company in West Australia. Salary £250 per annum. Apply to Box 61, Post Office, Oldham.

——— The Liverpool Salvage Association require a practical engineer to act as superintendent of steam pumps, electrical installatoins, &c. Salary, £150 to £200 per annum. Applications to the Chairman, A 20, Exchange-buildings, Liverpool, by June 10th.

BUSINESS FOR SALE.—Mr. John M. Macleod, C.A., of 101, St. Vincent-street, Glasgow, has for disposal the old-established business of electrical engineers, bell hangers, &c., carried on by Mr. J. Scott, under the style of D. and G. Graham, at 130 and 140, Douglas-street, and Byars-road, Glasgow, together with the whole of the stock-in-trade, plant, machinery, &c. Offers must be sent in to Mr. Macleod by June 14th. Some further particulars appear in our advertisement pages.

DISSOLUTION OF PARTNERSHIP.—Messrs. Kiesow and Wendt, globe and shade manufacturers, of 25, Fore-street-avenue, London, E.C., have dissolved partnership. Mr. Wendt continues the business in his own name.

——— Messrs. J. A., F. J. and A. H. Lea, who have hitherto carried on business as electrical and general engineers at Pengwerne Works, Shrewsbury, under the style of Lea, Sons and Co., have dissolved partnership. Debts by Messrs. J. A. and F. J. Lea, who continue the business as Lea, Son and Co.

LIQUIDATION.—At a meeting on May 22nd it was resolved that Sarsons (Limited), electric light globe and shade manufacturers, of Birmingham, be wound up. Mr. J. Squiers, C.A., 21, Bennett's-hill, Birmingham, has been appointed liquidator.

BANKRUPTCIES.—Loftus John Barnacle, formerly carrying on business as Hall and Co., electrical engineers, South John-street, Liverpool, passed his adjourned examination in bankruptcy last week.

AGENCY.—Messrs. Francis and Spilsbury announce that they have taken up an agency for the well-known manufactures of Mr. A. P. Lundberg.

G. KYNOCH AND CO. (LIMITED).—At the meeting of this Company, on Wednesday, the Chairman (Mr. Arthur Chamberlain) announced that their new works at Arklow were lighted throughout by electricity, gas-engine power being used. They had laid down gas-producing plant, and the engine drove a large dynamo which distributed light and power through the 170 acres covered by the Company's works.

BELL'S ASBESTOS COMPANY (LIMITED).—Mr. W. Claude Johnson, M.I.C.E., of the firm of Johnson and Phillips, has been elected a Director of this Company.

ELECTRO-PLATING OF SHIPS' HULLS.—Mr. J. H. Cox, engineer, of Greenock, is stated to have invented and patented a rapid method of electro-plating the hulls of iron and steel ships. The largest of vessels can be operated upon in dry dock in about a week. The chief object of the invention is the preservation of ships' bottoms from corrosion and fouling, and an experiment upon the floats of a large passenger steamer are said to have showed, after a trial of three months, that the copper was clean and free from fouling, while those parts unplated were found to be very foul.

ARC LAMPS.—We are informed that Messrs. Drake and Gorham will, in a few weeks, put on the market the "Jandus" arc lamp, which, the makers state, will burn for 200 hours with one pair of carbons.

MESSRS. CLARKE, CHAPMAN AND CO. (LIMITED).—This firm report that they are very busy in their electrical department. They have several orders for ship-lighting plants in hand, including one from the Admiralty for the complete installation for three of H.M. cruisers. This firm have also erected at the shipbuilding yard of Messrs. C. S. Swan and Hunter, Wallsend, an overhead traveller and jib crane, worked electrically, which serves to deal with all

Digitized by Google

the lifts required in building steamers, under an overhead erection of girders, &c.

A New Wire-Wound Steam Pipe.—A wire-wound steam pipe, consisting of an inner thin shell of steel or wrought iron, overwound with tough wire, one-eighth of an inch or less in thickness, has been patented by Mr. D. R. Smillie, of Glasgow. Tests of this pipe were recently carried out in the presence of Prof. Forbes, Mr. Harding, of the Admiralty, and several other gentlemen, at the works of Messrs. Mechan and Sons, of Elliot-street, Glasgow. These pipes are claimed to be stronger, lighter, and less costly than the pipes in general use.

The "Trusty" Oil Engine.—We hear that this engine, which has several times been favourably referred to and described in this journal, is now being made for greatly increased horse-powers, and that the prices have been reduced. The great convenience of the oil engine as a small motive power for isolated electric light and other installations is now fully recognised; and it is not less certain that, with oil even at its present somewhat high price, electric current can be obtained very cheaply by this means. One of the merits of the "Trusty" engine is that it will work with either Russian, American, or Scotch burning oils, and that the highly explosive petroleum spirits are not required in it. It seems that the engine gives better results with Scotch or American burning oils than with "Russolene," but as the former are far more commonly met with in this country, especially in the rural districts, where oil power is mostly required, there is more advantage than disadvantage in this fact.

Catalogue.—Messrs. R. Hornsby and Sons (Limited), of Grantham, have sent us a copy of the catalogue of their new Type B water-tube boiler. The general appearance and arrangement of this steam generator is not altogether unlike the type of water-tube boiler with which electrical engineers are now so familiar; but there are some very important modifications. The chief of these latter will be found in the arrangement of the mud-drum and return tube from the steam drum. The return-tube is carried vertically down from the back of the steam drum to a point below the level of the bottom of the lowest of the sloping water tubes. At this point it communicates with the bottom tube, as well as with the mud drum. The effect is to carry the circulating water to the bottom of the water-tube stack, instead of discharging it from the return tube into the top of the back header, as in some well-known boilers.

Ayr.—At the last meeting of the Town Council, on the recommendation of the Lighting and Hall Letting Committees, it was resolved to wire for the electric light the Town and Council Halls and Committee Room, together with the other municipal and police offices. The Committees further recommended that the expense of wiring the municipal offices be borne by the Common Good, provided the cost of the wires and fittings for the police offices be paid by the Police Commissioners. A long discussion on this part of the Committees' recommendation ensued, and Mr. Beveridge said that, although the matter was not a large one, there was a most important principle involved in it, namely, that tenants were to be expected to introduce the electric light into their landlord's premises, and he therefore moved that the latter part of the recommendation be not approved of. In reply, Bailie Ure said they were going to wire other buildings in the town, and he did not see why the Police Commissioners should be put on a different footing to others. It was also announced that two letters had been received, stating that the correspondents would take electric current if the Commissioners were willing to wire the buildings and supply the necessary fittings, they paying 5 per cent. on the cost of the fittings. A motion embodying this principle was finally adopted.

Bangor.—At the meeting of the Town Council, on Wednesday, on the recommendation of the Electric Light Committee, Mr. F. H. Medhurst was appointed consulting engineer to prepare a preliminary report and advise the Committee generally on the electric lighting question, at a fee of 25 guineas.

Belfast.—At the last meeting of the Electric Light Committee it was reported that applications for the supply of electric current had been received from the Northern Counties Railway Company and the Ulster Hall Company, and as an extension of the present mains to those districts would be necessary before the Committee could comply with the demands, the electrical engineer (Mr. V. A. McCowen) was instructed to make inquiries as to the probable demand for lighting and to report thereon at the next meeting.

Bolton.—Mr. W. J. G. Clerk, Local Government Inspector, held an inquiry this week on the application of the Corporation to borrow a further sum of £17,300 for electric lighting purposes.

Bray.—Notice of opposition to the Improvement Bill has been given by the Dublin, Wicklow and Wexford Railway. The Town Commissioners consider the opposition vexatious and unreasonable.

Brighton.—The pier or jetty erected by the Brighton and Rottingdean Seashore Electric Railway Company as one of the termini of the new electric line was opened on Saturday last, and it is expected that the line will be completed in August next.

Chelmsford.—At the last meeting of the Town Council the Lighting Committee recommended that the sanction of the Council be given to the transfer of the Provisional Electric Lighting Order from Crompton and Co. (Limited) to the Chelmsford Electric Lighting Company (Limited), and after a rather acrimonious discussion the recommendation was adopted.

Cheltenham.—A very satisfactory report is made of the working of the electric light machinery, and it has already been found necessary to extend the mains in order to meet the demands for current. An additional main is to be put down to a portion of the town outside the compulsory area at an estimated outlay of £1,300.

Church and Chapel Lighting.—St. Agatha's, Portsmouth, is to be lighted by electricity, and the success of the installation at the chapel at Elm-grove has led to the desirability of its general use in ecclesiastical buildings throughout the Portsmouth district being recognised.

Coventry.—At the last meeting of the City Council a report of the Electric Lighting Committee was discussed, which contained detailed instructions for the management of the electric light undertaking. After some discussion a clause providing for an annual financial return was added to the report, and in this amended form it was finally adopted.

Croydon.—Gen. Carey, Local Government Board Inspector, held an official inquiry on Wednesday into the application of the Corporation to borrow £27,500 for electric lighting purposes.

Dover.—The Town Council have accepted the offer of the Electricity Supply Company to light Snargate-street by electricity. Ten lamps are to be provided at a charge of £300 per annum.

Electric Light at the Military Tournament.—In reference to a note on this subject in our last issue, we have received communications from Messrs. Crompton and Co. (Limited), and Messrs. F. A. Glover and Co., both claiming a share in the electric lighting at the Agricultural Hall. Messrs. Bergtheil and Young were responsible for the matter of our note last week, and they write us that the information supplied is quite correct, and that they have authority "to advertise as contractors to the Royal Military Tournament." Messrs. Crompton and Co. claim to have carried out the permanent installation at the Agricultural Hall, and Messrs. Glover to have made some alterations thereto.

Electric Organs.—The fine organ at St. Margaret's, Westminster, London, has recently been overhauled, and electric motors similar to those in use at the Royal College of Music have been adopted for blowing the instrument.

Fire Prevention.—The Chelsea Electricity Supply Company, in order to provide against danger of fire at their Draycott-place station, have fitted a number of Merryweather's improved terminal hydrants, which are connected with the water mains. Similar apparatus and accessories have been supplied by Messrs. Merryweather to the Metropolitan Company, the Brush Company, the Edison-Swan Company, and other electrical firms.

Fermoy.—Representatives from Mr. H. Simon, of Manchester, attended the last meeting of the Town Commissioners, and explained the terms upon which he was prepared to carry out the electric lighting of the town. Mr. Simon submits two schemes, one to carry out the work at his own expense, and the other for the carrying out the scheme on a system of deferred payment by the Commissioners. The Board consider these propositions fair and reasonable, and a decision in the matter is to be come to on an early day.

Fulham (London, S.W.).—The Vestry Clerk has been requested to invite three electrical engineers (to be selected by the Electric Lighting Committee) to state their fees for preparing reports on, and estimates of the cost of, the installation and maintenance of the electric light for the parish, in conjunction with a refuse destructor scheme. The Committee have asked Prof. W. Garnett to advise them on the selection of an expert.

Gas Pipes.—It is said that Chicago is so grid-ironed with gas pipes that no more can be laid in the middle of the streets. The side-walks will be requisitioned in the event of more pipes having to be laid.

Halifax.—Mr. T. P. Wilmshurst, the Corporation electrical engineer, is reporting upon the proposed extension of the electric lighting mains to the Skircoat district. It is also under consideration to extend the electric light to the Halifax New Infirmary.

Hammersmith (London, W.).—At the last meeting of the Hammersmith Vestry the Electric Lighting Committee reported that the sub-committee which was recently appointed had visited the electric lighting installations at Chelsea, Ealing, St. Pancras and Portsmouth, and had carefully considered the various systems in use at those and other places, but they could not at present advise the adoption of the report presented by Messrs. Morgan Williams and King. The sub-committee recommend the Vestry to advertise

Digitized by Google

for complete schemes and tenders for the necessary plant for lighting the compulsory area, and that when such tenders and schemes are received the Vestry consult one or more engineers to advise them. This recommendation was agreed to.

Holbeach.—At their meeting on Tuesday the Urban District Council had under consideration the tenders recently received for lighting the streets of the district (by oil, gas, or electricity). The oil tender amounted to £140, the gas tender to about £165 (£2. 3s. per lamp, or 4s. 2d. per 1,000ft. consumed), while the electric lighting tender was £210 per year for a period of seven years. It was finally decided to adopt a penny wise and pound foolish policy by accepting the gas tender.

Hull.—The Electric Lighting Committee having considered the new Board of Trade Regulations, think that there are many objectionable points to be raised, and in this view are supported by the Electric Lighting Committee of the Borough of Lancaster. Exception is taken by both bodies to the distance limit of the supply area, which is considered to act detrimentally upon the application of electricity to tramway purposes, and upon this question the Hull folks feel strongly, as complaints are general of the parlous condition to which the present tramway system has drifted.

Ilfracombe.—The District Ccuncil have received a letter from Messrs. F. W. Ball and Co., of Bristol, asking if the Council had any objection to the starting of an electric lighting station, but the Council have replied to the effect that they wish to retain the electric lighting powers in their own hands.

Lancaster.—At the last meeting of the Electricity Supply Committee of the Town Council it was decided to extend the electric light mains in several districts at a total estimated cost of £2,035.

Medical Electrical Institute (Limited).—The official report of Mr. J. C. Stewart, official receiver and liquidator in this failure, is issued, and shows liabilities of £11,614, with an estimated deficiency of £5,472. The report enters into a lengthy review of the formation of the Company on the ashes of Harness's Medical Battery Company, which concludes as follows :—"Upon the commencement of business by the new Company advertisements seem to have been inserted in various newspapers upon a considerable scale, in the hope that, as a result thereof, the demand by the public for the medical and electrical appliances sold by the Company would greatly increase, it appearing that the former prosperity of the old Company was in a large measure due to a system of extensive advertising. In this hope, however, the Board were disappointed—the secretary states that the advertisements did not produce sufficient business to pay expenses." While it is satisfactory to find that this attempt to resuscitate a concern which was proved in court to be a gigantic fraud upon the public was unsuccessful, it shows clearly that influential organs of the press are not above inserting advertisements which can only serve as a snare for the unwary. In this case the public had been put upon their guard ; little thanks for this is, however, due to the principal organs of public opinion.

Middlesborough.—At a meeting of the Electric Lighting Committee of the Corporation on Wednesday, it was agreed to recommend the Council to light the town by electricity at an initial estimated cost of £25,000, for which borrowing powers are likely shortly to be sought.

Newcastle-on-Tyne.—The Electric Light Committee of the Town Council have considered the report of Prof. A. B. W. Kennedy (abstracted in our issue of the 17th ult.) on the proposed purchase by the Corporation of the undertakings of the two local electric light companies, and they recommend the Council not to purchase the rights of the companies on the terms set out in the report. Although the Committee have come to this conclusion, they have instructed the Town Clerk to make inquiries concerning the best means of providing an independent electrical supply, and the Committee will afterwards consider the advisability of obtaining powers therefor.

Obituary.—We have to announce the death of Mr. W. C. Deeley, Chairman of the Electric Light Committee of the Chester City Council. The deceased was Managing Director of the Dee Oil Works (Limited).

Oldham.—The Electric Lighting Committee have prepared their statement of accounts for the year ended March 25th last, which shows that the expenditure on capital account during the year to have been £608. 2s. 1d. The total capital expenditure to date was £25,380. 1s. The gross revenue for the year amounted to £1,915. 16s. 4d., and gross expenditure to £1,271. 18s. 3d., or a balance of £643. 18s. 1d. The interest on loans was £643. 3s. 9d., and the amount set aside for sinking fund was £153. 6s. 9d., thus making a deficiency on the year's working of £152. 12s. 5d. The price for electric current had been 6d. per unit to all consumers. The amount sold to 55 consumers has been 66.998 units, and the number of meters fixed on March 25th was 62. The number of equivalent 8-c.p. lamps supplied was 8,940, an increase of 5,021 over the previous year. During the year the supply mains at the Bottom-o'-th'-Moor were extended 180 yards. The total length of mains is now 4,576 yards. The Chairman and other members of the Committee have expressed their great satisfaction at the report, and have complimented the officials of the electric light works upon the success of their efforts. The Committee have decided to apply for powers to borrow a further sum of £15,000 for extensions.

Portsmouth.—In this town and the surrounding district the electric light is rapidly overtaking gas, and is coming into quite general use. The Asylum Committee have resolved to introduce electric light into the huge establishment at Milton, where the gas bill is £700 per annum, and the electric light fittings for which are estimated to cost £550. The Clarence Esplanade pier is to be lighted electrically, and throughout the municipal buildings gas is being superseded wherever possible. The many advantages of the electric light over gas are obtaining full appreciation in this town.

Provisional Orders.—The Stirling Electric Lighting Provisional Order has been passed by both Houses of Parliament. The Bill promoted by the Southampton Town Council has been read a second time by the House of Lords and referred to a Select Committee.

South African Telegraphs.—In his speech on the opening of the Transvaal Volksraad last month, President Kruger said the Government proposed to lay before the Volksraad a contract entered into between representatives of the Eastern and South African Telegraph Company and the Transvaal Government, whereby, by granting an annual subsidy to the Company, a considerable reduction in the charges for cable messages would be effected. Since this measure would be of great benefit to the population, the Government hoped the Raad would approve of its action.

St. Pancras (London, N.W.).—At the last meeting of the Works Committee of the Vestry it was stated that an application from the London Hydraulic Power Company for leave to lay mains for the service of business premises in Charlotte-street, to extend along Tottenham Court-road, Windmill-street, and across Charlotte-street, had been received. Mr. Matthews said that as the Electricity Department could supply motive power, it was unwise to give permission to a private company to tear up the streets merely for one customer, and it was resolved to forward the letter to the Electricity Committee for their consideration and report.

Telegraph Clerks' Grievances.—At a meeting of the Edinburgh Telegraph Clerks' Association, held last week to consider the recent decision of the Postmaster-General in regard to the appointment of a committee to inquire into their grievances, resolutions were passed expressing regret that the Postmaster-General has not seen his way to grant an inquiry into their case by a Parliamentary Committee, as was done in the other branches of the Civil Service ; and that with a view to mitigate the entire want of confidence which a departmental committee inspires, this meeting urges that both in the interests of the public and of the service the inquiry be public, and that while the telegraph case is being considered at least one working telegraph clerk be placed upon the committee.

The Telephone in Dublin.—A meeting of the members of the Mercantile Association who are subscribers to the telephone was held last week to discuss the grievances of the subscribers. The meeting, which was influentially attended, was presided over by Mr. Councillor Graham, who said they were aware that a serious breakdown had taken place in their telephonic communication, which lasted for 10 or 12 weeks, and had caused a serious loss to the mercantile community of the city. They complained that the National Company had disregarded their protests, and had bound them to the letter of their contract to pay for the telephone whether it was in usable order or not. He considered this an unreasonable position for the Company to take up, and he thought they should not demand the whole year's rental. Subscribers did not claim compensation, and were willing to say nothing about the serious loss they had sustained, but they did complain that, in addition to this loss, they were compelled to pay the Company for a thing they were not in a position to supply. This was a view of the question which deeply concerned telephone subscribers throughout the country, and perhaps this was the reason the Company had met their request with a *non possumus*. Their complaint was that when the breakdown occurred the National Company did not act with expedition, which they considered was a serious breach of contract on the part of the Company, who should use reasonable care, first to preserve the wire, and next, if a breakdown did occur, to have them repaired and put into working order immediately. There were other grievances, including the inattention of the operators and the contact of the subscribers' wires, which cause serious delay. Mr. T. Edmondson proposed a resolution embodying the complaints enumerated by the Chairman, and urging all subscribers to pay only for the time during which their telephones had been in working order. He said there was no desire

Digitized by Google

to oppose the Company in any way, as it was to the subscribers' interest to work amicably with them ; but the unreasonable conditions of the National Company necessitated their taking steps to protect the subscribers' interests. Mr. Malcolm Inglis proposed that a guarantee fund should be established to fight a test case, and this proposal met with the sanction of the meeting, which at once subscribed upwards of £100, on the understanding that, if the Company met the Association in a reasonable manner, no necessity would exist for further proceedings.

TUNBRIDGE WELLS.—The Electric Lighting Committee have adopted Mr. Preece's recommendation that the electric light mains should be extended along Mount Ephraim, Monson and Calverley-roads, at an estimated cost of £630. 10s. The Committee have also resolved to engage Mr. Preece to prepare plans and estimates, and to do all work required from the electrical engineer up to the obtaining of the sanction of the Local Government Board to the additional loan of £12,000, which the Town Council recently decided to borrow for electric lighting extensions, including attendance at the public inquiry, and that he be paid for these services 2½ per cent. upon the amount of his estimate, it being understood that in the event of the Council desiring Mr. Preece to undertake the superintendence of the carrying out of the works covered by the new loan he will give the same services as he has done in respect of the present works for an additional 2½ per cent. on the amount expended.

WANDSWORTH (LONDON, S.W.).—The General Purposes Committee of the District Board of Works have passed resolutions approving of the proposed laying of conduits for electrical conductors by the County of London Company, subject to certain conditions as to the work being executed to the satisfaction of the Board's Surveyor, &c. Mr. Dunkley, in discussing the Committee's recommendations, said that the residents in the district were earnestly awaiting the introduction of the electric light, and the opposition would prove futile.

WAREHOUSE LIGHTING.—The *Drapery World* points out that the use of the electric light in wholesale and retail drapery houses has been much increased during the past 12 months, owing to its having been found both healthier and cleaner than gas, as well as more convenient. The extensive range of warehouses of Messrs. John Howell and Co. (Limited), which have large basement spaces to be lighted, have recently been installed with the electric light, a complete plant having been put down under the supervision of Mr. Albion T. Snell, of Suffolk House, Cannon-street, E.C. The motive power is supplied by a 12 nom. H.P. Crossley gas engine, which drives a 12-unit dynamo, and the plant includes a battery of accumulators. At present 200 incandescents are used.

YORK.—The Streets and Building Committee, in reply to a letter sent to Prof. Kennedy, have received a reply to the effect that, as their request involves a deliberate opinion from Prof. Kennedy of the best system of lighting the city by electricity, he is unable to give this opinion without a special examination of the city and its requirements. A special meeting of the Council is to be called for June 17th to further consider the tenders sent in for the electric lighting of the city.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

COMPANIES' MEETINGS AND REPORTS.

Consolidated Telephone Construction and Maintenance Company (Limited).

The fourteenth annual ordinary general meeting of this Company was held at Winchester House, Old Broad-street, yesterday (Thursday), under the presidency of Mr. C. L. W. FitzGerald.

The SECRETARY (Mr. Charles Curtoys) having read the notice calling the meeting, the report of the Directors was taken as read.

The CHAIRMAN said: The report which we present to you to-day commences by showing you the operations of the past year, the manufacturing profit being the sum of £1,403, and the amount available for disposal—bringing into account the money we brought forward—is £2,866, from which we propose to pay you a dividend of £1. 10s. per cent., leaving a balance of £1,236 to carry forward. Now, gentlemen, we always have to refer to one subject—competition—which becomes more and more severe. What I discover is this—that our wages come to pretty much the same, and the amount we expend on materials to very much the same, but somehow or other, at the end of the year, we always have less profit. The amount we sell in gross means the same quantity of stuff pretty well, but its value is less. The year before last it was £17,000, last year it was £15,000, and this year it is £13,000; that is roughly speaking, of course. What I personally consider is that we are the victims of free trade, foreign competition, and high workmen's wages. There is no getting away from that. The telephone business is not a business which you can, as I may call it, ram down people's throats. The people who purchase the telephone are limited in numbers, and you cannot keep trying to sell telephones to people who have no use for them. A gentleman who buys a telephone cannot put it up for himself. In fact, your customers are, and always will be, limited, and that is one of the difficulties of this business. As to wages, however, we find that the lease of the factory is up at the end of the year, and we propose to move away from London, if we can get a suitable place, where wages are lower, where we hope to get coal cheaper, and where, possibly, steadily holding our own manufactures, we shall be able to make more profit for you. In addition, we have entered into an agreement which may turn out very valuable. It is in connection with a novel form of electrical battery, and we have entered into this agreement with the patentees of the capsule battery. The invention being new, it will, of course, require a very considerable amount of pushing to sell to the various people who are likely to use it; but with that we have nothing to do. We have to manufacture for the Capsule Battery Company, they doing the canvassing and getting the orders, but being bound to give us any order they receive for the next 14 years, or, I should say, for the term of the patent. I can see in that the possibility of this Company reaping a large profit. It is a very ingenious little article, and will do all sorts of things. It will fire a mine; it can be used for medical batteries, for ringing bells, and for electrical brushes. It can, in fact, be applied to a great many things where electricity is used. The next matter, which I will not go fully into now, is the question of our being able to manufacture things other than electrical, but that will come up at our extraordinary general meeting afterwards. I now come to what I consider the most important point in this report—namely, the lawsuit in Belgium, undertaken in conjunction with the Edison Gower-Bell Telephone Company, against infringers of the patent held by the Company, which resulted in a successful appeal against the previous decision, and the Court now has ordered a claim to be sent in for damages. Now, gentlemen, I think it would be well if I were to give you a slight history of this action; perhaps there are a good many shareholders who do not know anything about it. When my colleagues and myself in 1884 came into the management of this business we found that we—or rather the Edison Gower-Bell Telephone Company—had got a patent in Belgium, and that some people in that country were using our patent. I went to Belgium in 1886 to examine into this question, and I thought—and we all thought—that as our patent was extremely good, the people who were using it ought to pay us a royalty. I remember that at one of our meetings you passed a resolution authorising us to go into the actions, which commenced in December, 1886—nine years ago. After several failures at law we resolved to appeal, and in January, 1894, appeal proceedings commenced at Liège. In June, 1894, the Zurich company against whom proceedings were taken were found in damages and costs, which we have since been trying to get assessed. That means that we have finally won against this particular company, and we were ordered to send into the Court our claim for damages. Of course we did that as quickly as we possibly could, and since then—it is another year—we have been trying to force these legal gentlemen on either side to say that we have got no damages or that our damages are substantial, as the case may be. We have done the very utmost to expedite this lawsuit, and one can hardly believe it was possible for it to last so long. We do not know what we can do, but we keep on worrying the people over there. What damages we may ultimately get I cannot say. All that I can hope with regard to this particular point—which is really an important one to us—is that we may have something definite to tell you by the next time we meet. I now come to a paragraph which I hope will please the shareholders, namely, that the Directors have resolved, although our fees are charged in the accounts, to defer the payment of them. The remaining subsidiary company which we are interested in has again shown satisfactory progress, and when I come to the figures I will show you that it has perhaps done more satisfactorily even than it looks. Our trading account, as I have already told you, shows a profit of £1,403, which is considerably less than it was last year, when it amounted to over £3,000. The interest from our investments is about the same, with this exception that we received a large sum of money from the Austrian Company. On the other side there is not much difference to call attention to. The travelling expenses are slightly more than they were last year, and the income-tax is less. The legal expenses, I regret to say, are higher, but that is on account of the new business—the matters arising through the agreement and examining those things which had to be inquired into. The amount carried down is £606, to which we add the £1,301 balance of the revenue account from March last year, less the dividend passed by the shareholders at their meeting on May 31st following; the unclaimed dividends forfeited, £77, and the legal expenses *re* the Belgian patents £1,015. This sum represents the disbursements made in the lawsuit and charged against the profit in previous years, but now held up as recoverable. In respect to the sum we have charged our accounts with from time to time in connection with the Belgian lawsuit, we have decided, with the consent of our auditor, to write back that amount as profit taken from the shareholders at various times, the sum being now fairly recoverable in the lawsuit. With that amount we are enabled to carry down the sum of £2,866. We have made a little alteration in the accounts, for we have put the Edison Gower-Bell dividend, which has not been paid, to a revenue suspense account, instead of putting it up in the revenue account as so much due to us. That appears also on the *contra* side. The item of plant and machinery stands at £5,642 against £5,479. The next item is the cost of the installation of private lines. We spent this year in putting lines for subscribers to our private wire system £385, as against £399 last year. Our stock of instruments on hand is £7,296, against £7,422. Of our subsidiary companies, the Anglo-Portuguese Company last year owed us £5,170, but this year this Company owes us only £3,094. In other words, it has paid over £2,000 to us for back money that was owing. By other companies and persons we are owed £2,506, as against last year £2,165. The expenses connected with the patents represent the total expenditure on the lawsuit in Belgium—£1,691, and that, ranging over nine years, is not a very large amount. I do not think there is any other item to refer to except the loans. Last year we had £600 loaned to the Edison Gower-Bell Company, and this year that has been raised to £1,080, and we have also loaned the Capsule Battery Company £1,000 to take out foreign patents, of which we shall probably get the benefit by manufacturing the apparatus. On the other side of the balance sheet there is a very gratifying item. This year our creditors only amount to £757, while last year the amount was £2,194. The balance of net profits to March 31st was £2,866, as against £3,484 last year. In our valuation of securities there is an item of £500 for our shares in the United River Plate Telephone Company. Those shares in the market do not stand at that value, or anything like it; but when I tell you that but for the premium on gold in the Argentine Republic that Company would be paying us 13 per cent., I do not see that there is any harm in letting this item stand in the balance-sheet at £5,000, although it may only be worth £2,000. As I have always said, if we write down we must write up. I now propose the adoption of the report and accounts, and the payment of the dividend.

Sir ALEXANDER ARMSTRONG, K.C.B., seconded the motion.

Mr. BUCK said that to his mind the Company was in an unsatisfactory condition. He thought the Chairman had been most explicit with them, and that he and his colleagues on the Board had done all they could for the shareholders. He would like to know the opinion of the Board with reference to the actual value of their holdings in the subsidiary companies.

Mr. C. WOOLLEY said he felt indebted to the Board for looking elsewhere with the object of making profits in the face of existing difficulties. There was a great agitation at the present time with regard to the telephone, and their Company might come in for a share of the good things which, it was expected, would be going. As regarded the value of their goodwill and their interest in subsidiary companies, he understood that the Chairman had spoken with great care. With reference to the lawsuit, there were possibilities which might make the expenditure which had been incurred of £1,600 extremely valuable. Time after time they saw those who infringed patents brought to book and have to pay very handsome sums in the shape of royalties. As regarded the question of Directors' fees, he had been associated with a great many companies, and he always regretted where good suit and service was rendered that it was not properly compensated. He deplored the necessity which the Board had most manfully recognised in taking up the position they had done with respect to their fees. He wished to know, with respect to the £3,750 due to them from the Edison Gower-Bell Telephone Company, how did that sum come to appear in the accounts on the credit side, whether it was cumulative dividends, whether the amount represented a dividend payable, and, further, whether it was likely to be paid within a reasonable date. They held an enormous number of Ordinary shares in the Edison Gower-Bell Company and 20,000 Preference shares, but he saw no credit in respect of either for dividend.

The CHAIRMAN, in reply, said that the Directors felt that the report was not satisfactory, but they could not do more. As regarded the value of their holdings in subsidiary companies, they had £10,500 in 8 per cent. debentures of the Anglo-Portuguese Telephone Company. That was an asset which was worth a good deal of money if they could only get any one to buy it. Then there were their 6 per cent. debentures in the same Company to the amount of £1,700. That was a security paying the interest regularly, but they could not sell it, and that was their difficulty. The shares held by them in the National Telephone Company they could sell. The value of their shares in the Edison Gower-Bell Company, which figured at £11,000 in the balance-sheet, was rather a difficult matter. He would like to say when a dividend on these shares might be paid, but if he were to do so he would be only telling something to people on the other side of the water. It

Digitized by Google

was not the cost of their factory that they complained of, but the cost of wages, coal, and raw materials generally. They undoubtedly paid far more wages in London than would be paid in Birmingham.

The resolution was then carried unanimously.

On the motion of Sir A. ARMSTRONG, seconded by Mr. HENRY GREWING, Mr. FitzGerald was re-elected to his seat at the Board.

Mr. J. G. Griffiths was re-elected as auditor at a remuneration of 60 guineas.

An extraordinary general meeting was subsequently held for the purpose of considering resolutions modifying and adding to the Articles of Association to enable the Company to manufacture, buy, sell, and deal in articles, apparatus and inventions in connection with the production, storage, transmission, or use of electricity, or to which electric power may be applied; to manufacture, buy, sell, and deal in mechanical apparatus, appliances and inventions, or parts thereof, whether connected with electricity or not, and to acquire and work letters patent and patent rights relating to such apparatus, appliances, and inventions; and also to sanction the alteration of the name of the Company to "The Consolidated Telephone Construction and Manufacturing Company (Limited)."

The CHAIRMAN stated that they found that the telephone business was too limited to enable them to make a profit, and they hoped the business they were going into would bring them better results. Of course they could not be sure of that, but as regarded the capsule battery, he felt pretty confident that it would prove advantageous to them. Anyhow, it seemed to the Directors that it was advisable to try and manufacture other articles, and make a profit out of them.

The resolutions were carried unanimously.

West Coast of America Telegraph Company (Limited).

The report of the Directors of this Company for the year ended December 31st last, to be presented at the eighteenth ordinary general meeting at Winchester House, London, E.C., on Tuesday, 11th inst., states:—

The gross income for the year 1894 was £21,753. 12s. 2d., as against £15,096. 4s. 3d. in 1893, and in order to provide for the payment of the debenture coupons, it was necessary this year to take £10,400. 12s. 9d. from the reserve. The total expenses were £20,154. 4s. 11d., against £19,632. 16s. 6d. in 1893. The sterling value of the local traffic for 1894 was again most seriously affected by the low rates of exchange, both in Peru and Chile, the value of the dollar in Chile having fallen as low as 10⅝d., and the average rate for the year was 12d., as against 14d. in 1893.

In view of the recent legislation in Chile, by which the paper currency of the Republic is to be replaced from June 1st by gold, on the basis of 18d. to the dollar, it may fairly be hoped that exchange in the future will not greatly fluctuate from that figure. It may also be anticipated that the use of the telegraph for commercial purposes will continue to increase.

The Company's cables and landlines, as well as the repairing steamer "Retriever," continue to be maintained in a state of efficiency, consistently with which every possible economy is practised with regard to the expenditure. The direct service between the Company's stations and Europe, via Madeira, appears to have afforded every satisfaction to the public. Mr. J. Denison Pender and Mr. Frederick Walters both offer themselves for re-election as Directors, and Mr. John Francis Clarke, the auditor, also seeks re-election at the meeting.

Hobart Electric Tramway Company (Limited).

The following is the report of the Directors of this Company for the year ended December 31st last to be submitted at the general meeting of shareholders to be held at College Hill Chambers, Cannon-street, London, E.C., on Tuesday next, at 12 o'clock:—

The Company entered upon the working of the line themselves as from April 1, 1894, and a great saving was thereby effected. Further economies, including costs of administration, are being carried out. The revenue, though not equal to the expectations formed at the formation of the Company, has been well maintained, notwithstanding the great depression that has prevailed throughout the Australian Colonies, and for the months of January, February and March of the current year shows a monthly increase over that of the corresponding period of last year.

A further issue of £5,000 Second Mortgage Debentures has been authorised, raising the total of Second Mortgage Debentures to £20,000.

The number of passengers carried by the tramway since the opening of the line in September, 1893, to March 31st last is 2,346,972, and the total number of car miles run is 554,316. Careful and exhaustive reports have been submitted by the Company's General Manager in Hobart, Mr. A. C. Parker.

The retiring Director (Mr. J. G. Bellamy) offers himself for re-election, as do the auditors, Messrs. G. N. Read, Son and Co.

NEW COMPANIES, STATUTORY RETURNS, &c.

VAL D'AOSTA ELECTRIC POWER COMPANY (LIMITED).—This Company was registered on May 27, 1895, with a capital of £80,000, in £10 shares, to carry on in any part of the world the business of suppliers of electric light and power in all its branches; to produce and accumulate electricity and other forces by the utilisation of water and other power; to make experiments in and public exhibitions of electric power and lighting, and electrical machinery and appliances; to carry on the business of electricians, electrical and mechanical engineers, and manufacturers of and dealers in every description of electrical apparatus, and to acquire the right to manufacture, put up and sell telephones, telegraphs, phonographs, and electrical apparatus. The subscribers, with 25 shares each, are:—Oswald Brown, civil engineer; Frederick A. G. Brown, merchant; Antonio Bigio, merchant; Niccolo Bruno, engineer; Philip Bright, engineer; R. F. Austin, solicitor; J. Hunter Jones, contractor; and Walter G. Kent, engineer.

ELECTRICAL OIL REFINING COMPANY (LIMITED).—An agreement has been made with F. B. Aspinall, electrical engineer, R. W. Hoar, G. H. Wise, J. Cecil Bull, and David Cook (vendors), which provides for the transfer to the Company of the vendors' interest in Patent No. 18,767 (1893) for improvements in bleaching, sweetening and purifying oils, provisional specification No. 11,324 (1894), for an improved process of refining cotton oil and separating colouring matter therefrom, and provisional specification No. 24,095 (1894) for improvements in obtaining coloring matters from cotton seed oil, and other like oils, in consideration for the allotment as fully paid to them of 1,493 £1 shares in the Company.

"ELECTRICAL PLANT" (LIMITED).—The annual return of this Company, made up to March 7, 1894, is filed. The nominal capital is £10,000, in £10 shares, of which 575 have been taken up. Of these 500 have been considered as fully paid, and the full amount of £750 has been called and paid on the remainder. Mr. H. Cuthbert Hall, consulting engineer, is Managing Director, and holds 515 shares.

ELIESON ELECTRICAL SWITCH (LIMITED).—The statutory return to October 9, 1894, is filed. The nominal capital is £5,000, in £1 shares, of which 3,506 have been taken up. Of these 2,500 have been issued as fully paid to C. P. Elieson, electrical engineer. The full amount has been called on the remaining shares.

CITY NOTES.

BELGRANO (BUENOS AYRES) GAS COMPANY (LIMITED).—Mr. C. P. Ogilvie, who presided at a meeting of this Company on Tuesday, said the consumption of gas in their district had increased 15 per cent. during the past year. The Company had incurred £500 expense in obtaining an Act of Parliament in order to preserve itself in Belgrano against the advent of electric light companies, but he did not think that at present the shareholders had anything to fear from electric light competition. The satisfying dividend of 1 per cent. was declared.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended June 2nd were £929 against £869 in the corresponding period of 1894, being an increase of £60. The total receipts for the half-year amount to £20,533, against £20,013 for the corresponding period of 1894, an increase of £520.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—This Company's estimated traffic receipts for the month of May were £2,017, against £1,594 in the corresponding period of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of May, 1895, amounted to £68,382, against £54,846 in the corresponding period last year, being an increase of £13,436.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of May, 1895, amounted to £44,620, and to £43,960 in the corresponding period of last year, being an increase of £660.

ELMORE'S GERMAN AND AUSTRO-HUNGARIAN METAL COMPANY (LIMITED).—The report of the Directors of this Company for the year ended December 31st last states that the second debentures have been reduced from £49,480 to £25,980 by redemption at a small cost in Preference shares. The accounts of the Metall Aktiengesellschaft show that additions and improvements to buildings, machinery and plant, increase in materials and stores in hand, and increase in the amount due from sundry debtors are the chief features. The amount due to sundry creditors is large, owing to the amounts payable to contractors on account of new plant. Although the new plant was not completed until the end of 1894, the sales had increased from £3,194 in 1893 to £8,131 in 1894, and the loss on factory account was practically nil. The working of the Company was greatly restricted by want of capital during the early part of the year, but with regard to the general work of the factory to date the Directors report satisfactory progress. Owing to various causes the rate of progress has not been so rapid as the Directors would desire, but the sales are over three times as great as for the same period last year. The report states that the Company are in receipt of an abundance of good paying orders, amongst which is the supply of copper tubes to the German Imperial State railways.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this Company for the week ended 2nd inst. amounted to £1,146, as against £830 in the corresponding week of last year, being an increase of £316.

REDUCTION OF CAPITAL.—Notice is given that a petition is to be heard by Mr. Justice Kekewich, on Saturday, the 15th inst., to confirm the resolution to reduce the capital of the British Electro-Medical Agency from £75,000 to £50,000, divided into 2,500 Founders' shares of £10 each and 5,000 Ordinary shares of £5 each. Mr. S. G. Spreat, 27, Nicholas-lane, London, E.C., is solicitor in the proceedings.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ended May 31st, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,659.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the half-month ended May 31st are £2,600, as compared with £2,412 in the corresponding period of 1894. The January receipts, estimated at £4,693, realised £4,756.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 891. [No. 7. Vol. XXXV.] FRIDAY, JUNE 14, 1895. PRICE SIXPENCE.

NOTES.

THOSE who are accustomed to compare the exhibits of scientific and artistic interest at the soirées given by the Royal Society from time to time will have observed that, as a general rule, the exhibits are more of artistic and less of technical interest on the occasions of the ladies' soirées, and last Wednesday's function formed no exception to the rule. Artistic exhibits abounded; but the number of electrical exhibits was noticeably small. Yet, what there were of the latter were intrinsically interesting; even though the majority of them had been on show in May. Undoubtedly the most attractive of the electrical exhibits was the POSTMASTER-GENERAL's demonstration of the new telephone trunk-line system connecting Edinburgh, Glasgow, Leeds, Belfast, Dublin, and Cardiff, all of which places were duly and successfully "called up." There had been the official inauguration of this telephone trunk system at the General Post Office earlier in the same day, and on both occasions speaking with each of these towns was remarkably distinct and loud, and singing, laughing, and even Scotch humour came through without any appreciable "distortion." Nor did inductance or capacity seem to be too formidable for the droning of the melancholy bagpipe.

OF the other exhibits, we may mention the collections of drawings of the electric arc, by Mrs. AYRTON, together with a number of carbons used in the researches to which these drawings relate. A 8-dimensional model, showing the surface which is the *locus* of the curves obtained by Mrs. AYRTON in these arc investigations, was shown by Mr. A. P. TROTTER. The electric furnace exhibited by Prof. ROBERTS-AUSTEN demonstrated the practical applicability of the electric arc in the metallurgy of highly refractory metals. Other electrical exhibits were made by Sir DAVID SALOMONS, Prof. RAMSAY—who showed spectra of argon and helium—Prof. EWING and Miss ALICE LEE. The last-named exhibitor showed a set of curves demonstrating the development, propagation, and and dying-away of Hertzian waves, and it is intended, when the set is complete, to have the curves photographically reduced and placed in a zoetrope, so that the phenomena may be optically demonstrated.

SINCE the meeting of the Electrical Trade Section, which was held on Tuesday to discuss the revised Board of Trade Rules for securing the public safety, wisely resolved itself into a Committee, a proceeding which was not inconvenienced by an over large attendance, we are only at liberty to state that the rules were gone through one by one, and received careful consideration; the treatment, however, was not sufficiently drastic to suit one gentleman present, evidently a lineal descendant of the inventor of "Pride's purge." We may add that the Board of Trade has courteously extended the time for sending in suggestions to the 15th inst., and that efforts are being made to ensure that the emendations proposed by the Institution of Electrical Engineers, the Electrical Trade Section, and the Borough Electrical Engineers assembled in council shall all be on the same lines. In any case the Board of Trade will be difficult to move. Without some common agreement as to the modifications to be proposed, the Department may very possibly afford the electrical industry an opportunity of solving the well-known problem of the immovable body and the irresistible force, with the latter factor left out.

As suggestions are the order of the day in this connection, we may be forgiven for hazarding one ourselves. A good modification of Rule 4, the idea of which is apparently to limit the magnitude of the disturbance caused by the breakdown of a long-distance feeder, would be to forbid any single line to carry more than a certain percentage of the total output of a station, a special exemption being accorded to stations with specially small outputs. To rigidly fix a certain maximum for all cases is both unnecessarily hampering future and irritating present central station engineers.

GENERALLY speaking, the Board of Trade, in its anxiety about the public safety, seems to have entirely lost sight of the public convenience. The automatic cutting out of every line and machine which may happen to be momentarily behaving abnormally, would conduce rather to an increased demand for gas than to safety. The first duty of a central station engineer is to maintain the supply. In the performance of this duty the Board of Trade do not appear disposed to afford him any assistance, except of an academic order. We have most of us at one time or another experienced the calm frame of mind which is brought about by the airy advice of a fashionable physician to a busy man to take a three month's complete rest at an expensive and far-distant health resort; beyond his purse and beyond his reach. Something of the same chastened mood may be expected to

Digitized by Google

follow on the cheery advice which the Board of Trade by implication gives to central station engineers, namely, to duplicate and triplicate everything, and thus set eccentric automatic cut-outs, *et hoc genus omne*, at defiance. It can be done, of course, if the public will only foolishly find the money.

THE old A. T. *v.* B. T. controversy, which was so fiercely fought out seven years ago at the Society of Telegraph Engineers and Electricians, and which has since burst forth at irregular intervals in semi-extinct volcano fashion, had one of its remittent eruptions last month at the Northern Society of Electrical Engineers, the occasion being the reading by Mr. J. C. HOWELL of an able and interesting Paper on "Uses of Accumulators." There were not quite so many polemics and hypothetical statistics last month as was the case in April, 1888, but what was lost in excitement and prophecy was more than gained in knowledge. So long as human nature remains what it is, it will probably continue to find a vent for its superfluous loquacity in controversy, and had the A. T. *v.* B. T. question not cropped up, probably the sine curve or some other such battle would have been more deadly. That there has been any controversy at all is, perhaps, due as much to the excessive ardour of the secondary batteries advocates as to the not unreasonable aversion of the average electrical engineer to filling up his station with imposing rows of glass vats filled with acid. Even in the pre-central station era of seven years ago, the advantages of storage were sufficiently obvious. But to-day, what with elaborate costs analyses, peaky load-curves, and ugly coal bills, even the most obdurate would hail a genuine means of storage as a relief. One can scarcely imagine our good friends the gas engineers throwing heretical doubts on the utility of the gasometer, but that is simply because its utility is so absolutely beyond dispute. When the advocates of accumulators are able to bring forth an electrical equivalent of the gasometer, the A. T. and B. T. controversy will become an extinct volcano. Meanwhile, the B. T. men must expect to see their claims very closely scrutinised. It may be quite possible to reduce one's generating expenses, say to 1½d., by the judicious use of accumulators, but with accumulators as we now know them, central station engineers have ever to be on their guard lest in effecting this economy they sink so much capital in acid-holding vats that the extra profit which thereby accrues is insufficient to pay the increased sum required for interest.

THE point raised by Mr. COWAN in the discussion on Mr. HOWELL'S Paper, a point which he elaborates in an article appearing elsewhere in the present issue, was, we think, effectually disposed of by Mr. HOWELL in his reply. Mr. COWAN argues that the only saving which accumulators can effect must be made on the units actually taken out of the batteries, and as these units are usually but a small percentage of the total units generated, therefore the saving on the cost of the total output must be very small. Leaving out of consideration the fact that the judicious use of accumulators enables, in some instances, an entire shift, or even more, as at Belfast, to be dispensed with, and that in all cases it tends to reduce the number of men required at a central station, it is obvious, we think that accumulators, if properly made use of, enable *all* the units generated to be generated by engines running at a tolerably close approximation to full load, an approximation which can only be secured otherwise by a very minute subdivision of plant; an expedient which in its turn introduces many fresh difficulties and sources of loss.

As is so often the case with the Northern Society, the discussion was of a thoroughly practical nature, the speakers being in every case actual or potential users of accumulators. We have of late heard much about high-rate-of-discharge accumulators; but, as Mr. RIDER pointed out, these would be still more valuable were they also capable of being charged at a high rate.

IN our "Correspondence" columns this week will be found a letter from Prof. ZICKLER concerning his electro-dynamometer, which we recently described. We are glad to note that Prof. ZICKLER has turned his attention specially to the elimination of the induction variation. The equalisation of the turns on the fixed and moving coils would reduce the self-induction of the instrument from its present value of 2·76 henrys to about 0·07 henry, if the same product of turns were retained. As this value of the self-induction, however, makes the induction variation practically *nil*, it would be possible to increase the turns, and thus reduce the current, without an undue self-induction. If Prof. ZICKLER finds it practicable, by the use of the aluminium coil, to approach equality in the turns of the fixed and moving coils without seriously affecting the accuracy of the watt readings, or increasing the weight of the suspended system, the value of his instrument will be very greatly enhanced.

IT will be seen from our "Legal Intelligence" this week that the Parsons turbine has again been invoked to stay vibration, the City of London Electric Lighting Company having, on Mr. FRANK BAILEY'S advice, decided to replace four of its vertical engines by steam turbines. The Company's appeal to the House of Lords in the action brought against it by Mr. SHELFER has, in consequence, been withdrawn. An engineering victory is always to be preferred to a legal one; it is often cheaper in first cost and always so in the long run.

IN our "Correspondence" column this week will be found an interesting letter from Mr. H. F. PARSHALL referring to our recent comments on Prof. H. J. RYAN'S Paper on "Improvements in Armature Ventilation." Mr. PARSHALL says that his own experience confirms our criticisms and statements; and his letter is a very instructive amplification of the views which we had previously advanced.

Conversazione of the Institution of Electrical Engineers.—The annual conversazione of the Institution of Electrical Engineers will be held in the Galleries of the Royal Institute of Painters in Water Colours, 191, Piccadilly, on Wednesday evening, July 3rd, from 9 till 12 o'clock.

Digitized by Google

University College, London.—Particulars are given elsewhere of the courses of instruction in mechanical, civil, and electrical engineering, which commence on October 1st, and are arranged to cover periods of two and three years.

Cable Interruptions:

	Date of Interruption.	Date of Repair.
Chorillos—Iquique	June 4th, 1895.	June 5th, 1895.
Mollendo—Arica	June 4th, 1895.	—
Laurenço Marques—Mozambique	June 9th, 1895.	—

Royal Institution.—At a general monthly meeting of the members of the Royal Institution, held on Monday last, the special thanks of the members were returned to Lord Playfair for his donation to the Fund for the Promotion of Experimental Research at Low Temperatures.

Damage by Lightning.—At Ardgay, last week, a gamekeeper was killed by lightning.——At Beauly, some people working on a farm were overtaken by a thunderstorm, and took shelter under some trees. Three of them were injured by lightning; their faces were burned, and all of them were more or less stunned.

The Chicago Lamp Tests.—Certain of the ancients believed in the existence of an ever-burning lamp. The *Electrical Review* of New York asks whether "it is possible the lamps submitted for test two years ago (at the Chicago Exhibition) are burning yet?" For no publication of these tests has yet been made.

Cambridge Engineering Laboratory.—Prof. Ewing announces that Mr. W. Mather, M.P., has promised to present to the engineering laboratory a 20-H.P. combined steam engine and dynamo of a modern high-speed type, specially adapted for experimental work. The engine is now in process of construction by Messrs. Mather and Platt.

Engineering Training.—A writer in the *Electrical World*, of New York, says that "the truth is that a first-class constructive engineer can be turned out in a year or two." In our opinion this is very far indeed from the truth; and the sooner young men realise the fact the better will it be for the future of the profession.

Royal College of Science (Ireland).—The next session will commence on October 7th, and entrance examinations for intending associates will be held on Monday, 17th inst., and on Monday, October 7th; the subjects are mathematics and elementary practical geometry. Some further particulars will be found in our advertisement pages.

A Mercury Rail Bond.—A novel form of electric rail bond has been proposed in America. The ends of the abutting rails are united by strips terminating in holes in the rail containing mercury. The holes are drilled in the side of the rail head with a downward and sideward inclination. Mercury is then placed in them to a suitable depth and the strips are driven in so as to enter the mercury and tightly close the holes.

Electric Tramway Competition.—While in New Haven, U.S.A., the effect of the electric tramway has been to reduce the number of licenced public omnibuses by 50 per cent. and the hacks by 30 per cent.; in Denver the electric tramway receipts have been terribly reduced by the 10,000 bicycles which are estimated to be used in that city, and the tramway company has had to reduce its expenses—otherwise, its servants' wages—to balance this loss.

Meeting of the German Electro-Chemical Society.—The annual meeting of the Deutsche Electro-Chemische Gesellschaft was held at Frankfort on the 6th, 7th, and 8th inst. Among the Papers read at the meeting were the following:—"Electrical Transmission of Power," by Prof. Ostwald; "Charging Accumulators by means of an Alternating Current," by Herr Pollak; "Calcium Carbide," with experiments, by Dr. Borchers; "On a New Electrolytic Analysis Method," by Dr. Jordes. Visits were also paid to the Pollak Accumulator Works and to the Gold and Silver Separating Works.

The Chicago and St. Louis Electric Railway.—But little, says the *Street Railway Gazette*, has been heard for the last year and a-half of the Chicago and St. Louis Electric Railway. Mr. Washington Adams, the projector, is quoted as saying that for the last few months the Company has been busily engaged in endeavouring to find a market for the bonds which the Company needs to sell before beginning the construction of the road. According to Mr. Adams, arrangements have now been made with Chicago bankers for placing $9,000,000 of the $10,000,000 worth of bonds to be issued.

The Light of the Future.—An American contemporary expresses its contemplation of the "light of the future" in the following extravagant rhapsody:—

> "When the sun's rays weaken, when the decay of a colossal planet is heralded to us, how shall we prepare for the inevitable darkness, or drive away the iciness of interplanetary space? The glow-worm has taught us its lesson; the will-o'-the-wisp is no longer a delusion. With a whip that science alone can control we will lash the ether until it gives to us the quivering light of dawn—the effulgence of the rising sun."

We really think the attention of the Royal Society for the Prevention of Cruelty to Animals should be called to this proposed wanton infliction of corporeal punishment.

The Ganz Company's Alternate-Current Patents.—Messrs. Ganz some years ago sued the local electric lighting company at Tours for infringment of their alternate-current system of parallelled transformers. The Court of Appeal at Orleans decided in favour of Messrs. Ganz, but the Tours Company carried the matter before the Court of Cassation, the highest tribunal in France, which has now given its decision, and confirmed the judgment of the Court below. A similar lawsuit, as we reported some time ago, was brought in Italy against Messrs. Siemens and Halske; this also has been decided in favour of Messrs. Ganz.

Atlantic Submarine Telegraphy.—On the 23rd ult. about 350 members of the New York Chamber of Commerce attended a special meeting of that body to witness the ceremony of the presentation to the Chamber of a picture commemorative of the work of the late Mr. Cyrus Field and his American associates in laying the first Atlantic cable. The picture represents a meeting of the Atlantic cable projectors in the house of Mr. Cyrus Field in Gramercy Park. The picture is life-size, the canvas being 9ft. by 7ft. The list of donors includes the Gould Brothers, Western Union Company, Mr. Cornelius Vanderbilt, Mr. J. Morgan, and about 50 others.

A Commercial Electric Furnace.—According to the *Canadian Electrical News*, the Montreal Electric Company have recently put up an electric furnace at the works of Messrs. Peck, Barry and Co. for heating bar iron intended to be converted into horse nails. The current at a potential of 1,040 volts is taken from the mains of the lighting company and is reduced to 20 volts by a Siemens transformer. The furnace itself consists of a carbon tube 2ft. 6in. long and 2in. in diameter. The bar of iron is slid through the tube, which is covered with sand. On a current being passed through the carbon, the iron is rapidly heated, 5ft. of the bar being brought to the proper temperature per minute.

Semi-Municipalised Tramways.—The London County Council have completed an arrangement with the London Street Tramways Company to lease to them the part of their undertaking which the Council has acquired for five years from August 1st, but determinable at any earlier day before 1898 by giving three months' notice, for a yearly rental of £5,729 and insurance against fire; the lessees to pay all rents and outgoings, and to work the tramways continually and efficiently. One clause of the agreement lays down that the Company is not "to employ any servant more than 60 hours in any one week, or for more than 10 hours per day upon an average of any two consecutive days, and to pay to the lessors £50 damages for every breach of this covenant."

Obituary.—Señor Don José Aparicio, who has represented the Direct Spanish Telegraph Company in Spain since its formation (more than 22 years ago), died at Madrid on the 6th inst. from heart disease. Señor Aparicio was for nearly 15 years in the Spanish Government Telegraph service before joining the Direct Spanish Company, of which he was one of the representatives at the International Telegraph Conference of Paris in 1890. He was also hon. secretary and treasurer for Spain of the Institution of Electrical Engineers. He was a man of remarkable business capacity, and was much esteemed by those with whom he had dealings, as was proved by the imposing

Digitized by Google

procession which followed his remains to the Cementerio del Este, at Madrid, nearly all the officials of the Telegraph Corps in Spain being present.

Electric Parcel Delivery.—A novel application of electricity has been made at Victoria Station, Manchester. For some time the necessity has been felt of increasing the facilities for dealing with the parcels business at the station, and an overhead tramway, extending from the old parcels office on No. 3 platform to No. 8 platform, where the new parcels department is now situated, has been constructed. This miniature tramway is suspended from the girders of the roof. Along the rails runs an electric traveller, capable of lifting and conveying a ton, but which is not used for more than half that weight. When parcels have to be transferred to or from the office they are placed in a hamper, and it is then lifted up to its place under the motor cab, which is under the control of a workman, who is able to stop it and let down or pick up a hamper at any point. At present only one set of rails is in use, but the Company are fixing a second pair to run alongside the first.

Light Railways Bill.—On Tuesday evening last Mr. Bryce formally moved the second reading of this Bill in the House of Commons. Mr. Strachey moved, "That, so long as light railways are constructed and maintained by Imperial subventions in Scotland and Ireland, no bill for the construction of light railways in England will be satisfactory which does not provide for like assistance from the Treasury." The agriculturists of the country strongly approved of the amendment he proposed. Mr. Grant Lawson seconded the amendment On Wednesday evening the debate was resumed by Mr. Grant Lawson, who said that the obstacle to the creation of light railways was not the expense of obtaining Parliamentary sanction to their construction, but the difficulty of raising capital for them. If private companies were to be started to construct and carry on these railways profitably, it would be necessary that they should have State aid. But if the House would not give State aid to light railways in England, would they face the only possible alternative? Would they grant the Directors of those railways power to charge rather higher rates than were charged by the great trunk lines which, with their big organised staffs, could naturally work much more cheaply than the small lines? Mr. Parker Smith said that, in his judgment, there should be a much greater power in the Bill in the direction of empowering the Board of Trade to relax the requirements. The hon. member was speaking at midnight, when the debate stood adjourned.

The Electrical Standardising, Testing and Training Institution.—We have received from the secretary of this Institution some particulars of the latest developments of its many-sided activity. In the standardising and testing departments the Institution undertakes to examine instruments and supplies, on behalf of manufacturers and users, as well as to inspect outside machinery and works. A useful adjunct to these departments is the suite of private testing rooms, where for a truly moderate fee anyone can pursue original or any other form of experimental work under the most favourable conditions. Another branch of the same class of usefulness is the lending out of sets of testing apparatus, so that the occasional or needy inspecting electrician is under no necessity to purchase expensive apparatus, but can hire it hot from the calibration room. Besides catering in these useful ways for existing members of the electrical profession, the Institution is also taking care that its ranks shall not become thinned, by providing a well-equipped and systematically managed training college. The motto here is "*γνῶσις καὶ πρᾶξις*," and to all appearances it is acted upon. The student receives three classes of instruction: (1) theoretical instruction in the lectures and class-rooms, (2) laboratory work, and (3) actual experience in workshops and electric supply stations. This is probably as far as any institution, other than a manufacturing engineering concern itself, can go in the direction of training up a young engineer in the way he should go. There are nowadays so many young engineers, so-called, who are far from being trained up in the way they should go, with the result that long before they are old they happily depart from our ranks. But the Faraday House Institution claims to have secured appointments for over 80 per cent. of its fully qualified students, which is a good record, even with the assistance of "affiliated companies."

Technical Instruction Conference.—The following letter has been addressed by the Secretary of the Society of Arts to representatives of Technical Education Committees, and others interested in the subject:—"Sir: It has been suggested to the Council of this Society that a useful purpose would be served if the Society were to afford to those who are interested in Technical Education in different parts of the country an opportunity of meeting together, and discussing the measures which the Society might take with a view to enlarge the scope of its present action in this matter, and thus aid local authorities in giving effect to recent legislation on the subject. There appears to be a lack of central organisation which might deal especially with such questions as the examination and inspection of classes. In spite of the valuable work which has been done by the City and Guilds of London Institute, and by other bodies, it is only in a portion of the subjects sanctioned as subjects of technical instruction that examinations are held. The wide field of agriculture and home industries is untouched; while no means are provided for anything like a general system of inspection which local authorities may call to their aid should they desire to do so. There are also other points with regard to which common action would be desirable, and the Council of the Society have, therefore, determined to hold a Conference of Representatives of the Technical Instruction Committees of the various County Councils and others, with the view of eliciting their views on the subject. It is proposed to hold this Conference on June 20th next, and to invite to it the Chairmen of the Technical Instruction Committees, or other representatives who may be delegated by such committees, and their directors or organising secretaries. I shall be glad if you will let me know whether you can yourself attend the meeting, and also whether your County Council will depute any members of its Technical Instruction Committee to attend."

Electric Lighting of the Side Streets of the City.—At the last meeting of the Commissioners of Sewers the Streets Committee presented the following report:—

"From time to time we have had under consideration the question of lighting the minor streets of the City under the electric lighting contracts entered into by your honourable Court in the years 1890 and 1891. These contracts provide, *inter alia*, that all streets, lanes and courts, other than those described as main thoroughfares, shall be lighted by means of 906 glow lamps, the prices being fixed at £10 per annum for lamps of 200 watts power and £5 per annum for those of 100 watts, the right being reserved to the Commissioner to change or alter any specified lamps as they may direct. With a view to determine the best method of lighting narrow thoroughfares, experiments were made in Aldermanbury and Basinghall-street with incandescent lamps of these capacities, but the result was by no means favourable to this mode of illumination, and a subsequent trial with alternating arc lamps in the latter thoroughfare proved of no practical value. We thereupon instructed Mr. Preece and your electrical inspector to formulate a scheme for lighting the minor streets where possible by arc instead of glow lamps, and a survey of the thoroughfares in question was made, and plans were prepared by Mr. Voysey with that object. The City of London Electric Lighting Company, however, having intimated their inability to furnish us with any reliable estimate as to the cost of giving effect to the proposal until further experience has been gained on the subject, we submit a report from the electric inspector, suggesting that certain experiments should be made to illustrate side by side three different methods of illumination, whilst every facility will be afforded to Mr. Voysey by the Company to check the actual cost of each system. It is proposed to light Bow-lane and the court leading out of it to Bow-churchyard by means of six "Sunbeam" incandescent bracket lamps, so arraged as to be capable of being switched on and off by the police. Watling-street, Bread-street, Friday-street, and Old Change are to be lighted by means of 11 centrally-hung arc lamps. The thoroughfares selected for the experiments being contiguous will afford the opportunity of practically testing the comparative efficiency and value of the alternating and continuous-current systems of arc lighting, as well as of the method of illumination by means of "Sunbeam" incandescent lamps, and of obtaining information as to the respective costs of running the same, the City of London Electric Lighting Company having agreed to charge only the actual cost to them of the work, which they estimate at about £386, independently of the charge for running the lamps, which your electrical inspector is of opinion will be about £1 per night. We beg to recommend that the proposed experiments be agreed to, and that the report be referred back to us to have the same carried out accordingly."

As the hour was late and several members had left the Court, the report was ordered to be printed and circulated and its consideration adjourned.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(*Continued from page 149.*)

Steam Engine Testing.

It is impossible, within the compass of the small space which can be devoted to the subject of steam engine testing, to do more than briefly describe some of the more important and common tests, and to indicate the chief points to be observed in making them, leaving the reader to consult more special works on the subject for fuller information. In testing a steam engine, the principal points which usually require to be determined are: the indicated and brake horse-power, or, if the engine is directly coupled to a dynamo, the electrical horse-power; the steam consumption of the whole engine at various conditions of load; and the quality of the steam supplied. As subsidiary points, it will be necessary sometimes to test the condition of the valve setting, to determine the amount of steam used in the jacket, and to examine the working of the condenser. If the steam is superheated, a separate trial of the superheater will be necessary.

Besides these tests, which from time to time may be made upon the engine, there are the continual tests which must be made in every well-regulated station. A properly managed electric supply station will be under a ceaseless condition of being tested. Careful check will be made upon the performance on the one hand, and upon the consumption on the other hand. The output of the dynamos driven by the engines will furnish some guide to the useful power developed by the engines themselves; and recording instruments, such as electrical energy meters and revolution counters, &c., will enable the amount of duty and performance of each set to be noted and recorded. A similar check will be made upon all those supplies, such as fuel, water, oil waste, &c., which have to be expended in keeping the machinery going. In this way the long-period efficiency of the steam plant and of its coupled machinery will always be easy of inspection, while the careful tabulation of the separate items will enable any incipient fault to be detected or the locality of any abnormally heavy waste to be discovered. The occurrence of such a fault will often give occasion to some special test, such as one or other of those which will now briefly be described.

Test I.

To Determine I.H.P.—In making a direct test of the indicated horse-power of a steam engine, it will be necessary to measure the following quantities: (1) the length of stroke, (2) the nett area of the piston, (3) the speed of revolution, and (4) the indicator card. If there are more than one cylinder on the engine, the test virtually becomes a measurement of the I.H.P. of each separate cylinder, care being taken to see that the indicator cards of the several cylinders are taken simultaneously, or else that the load and steam pressure are kept quite constant.

The length of stroke and the area of the piston, if not known, can easily be measured when the engine is not running. The former is best measured by noting the linear movement of a mark on the piston rod past a fixed point, such as a scribing point, when the engine is turned from the inside to the outside dead centre. If accurate measurement is desired, care must be taken to see that the engine does not shift over from one brass to the other at the crosshead and crank pin bearings while this is being done. The nett area of the piston is found by deducting the sectional area of the piston rod from the total area of the piston, if the engine has a tail rod or prolongation of the piston rod; but half of the area of the piston rod only must be deducted if there is no tail rod. Simple a matter as it may seem to measure the speed, there is generally a liability of introducing greater error by this factor than by any of the others. Where the engine is making only, say, one hundred or less revolutions per minute, an error of one revolution in the speed measurement causes an error of one per cent. or more in the final result. To reduce this error in the speed the counting may be carried on for longer than one minute; but there is then introduced the liability of the speed having changed during the count. During indicator tests the speed may be estimated in one of two ways: either by counting the revolutions or by noting the indication on a speed indicator or tachometer. The former can only be relied on if the conditions permit of a long count; the latter only if the indicator is well calibrated and if there is no belt gear to introduce a chance of slipping. On the whole, it is probable that indicator tests are far more frequently vitiated by want of accuracy in speed measurement than by even the errors of the indicator card.

The steam engine indicator usually consists of a small cylinder in which there is a freely-moving piston, the movements of which are accurately magnified by linkage and imparted to a vertically-moving pencil. The pencil moves over the surface of a vertical drum, mounted on the same frame as the instrument cylinder; and this drum receives a reciprocating motion on its vertical axis by means of an inextensible cord attached, by suitable reducing gear, to the piston rod. Thus, the horizontal linear movement of the drum past the pencil is an exact reproduction, on a small scale, of the movement of the engine piston. By connecting

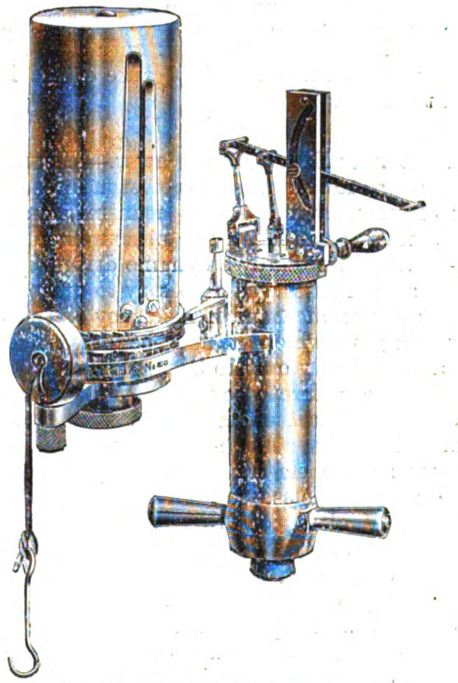

Fig. 70.—The Tabor Indicator.

the lower part of the instrument cylinder to the engine cylinder, and by placing a steel spiral spring of sufficiently perfect elasticity in the upper part of the former cylinder so as to cause it to press downward on the piston, it is evident that the movement of the indicator piston will reproduce the variations in steam pressure within the engine. A sheet of white paper clipped over the surface of the drum will be marked by the pencil in a continuous line, the shape of which will be the indicator diagram required; *i.e.*, the ordinates of the diagram will represent the steam pressure on the engine piston, and the abscissæ will represent the stroke. One form of instrument, known as the Tabor indicator, is manufactured by Messrs. Musgrave and Sons, and is illustrated in Fig. 70. The pencil linkage of this instrument is caused to produce a straight line motion by means of a curved slot and pin, as will be seen by the illustration. For descriptions of other forms of indicators, the reader is referred to "A Practical Treatise on the Steam Engine Indicator and Indicator Diagrams," by Mr. W. Worby Beaumont.

When the object of indicator rigging is once grasped, namely, that it has to transmit the motion of the piston in reduced facsimile to the drum, there will be no difficulty in contriving a form of rigging to suit any particular kind of engine and

* From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Digitized by Google

arrangement of engine room. Generally speaking, the points to be remembered are: that the theory of the rigging shall be approximately (it need not be absolutely) correct; that the joints shall be free from excessive looseness or back-lash; and that the members shall be rigid and strong enough to resist flexure and change of length. With these conditions fulfilled, the simpler the rigging the better; and it may be added that one way to eliminate forces which lead to flexure or distortion of the rigging is to have as little friction as possible.

Attention must be paid to the scale of the reduction of the piston motion, and to the scale on which the steam pressures are drawn by the pencil. The former is principally determined by the speed of the engine. It will, in general, be sought to obtain as long a diagram as practicable, in order to minimise the errors in estimating the area of the diagram, &c.; but if the length is too great in proportion to the speed, the movement of the drum will set up a reaction which will slacken the cord, thus distorting the diagram. With very slow-speed engines a full diagram, just clearing the drum stops, may be taken; but with high-speed engines the length of the diagram may have to be reduced to half, or even less than half, this amount. The latter is determined by several considerations, into which it is impossible here to enter; but it may generally be taken that a diagram of greater height than is fixed by the limits of pressure marked on the spring will be liable to error from imperfect elasticity of the spring. Again, with high-speed engines it is necessary to work with a lower diagram than with engines of lower speed, because of the inertia reactions within the indicator.

Test II.

To Determine Brake Horse-Power.—Electric power engines may be tested for brake horse-power in three ways, in general: either directly, by means of a transmission or an absorption dynamometer, or indirectly by measurement of the electrical horse-power given off by a dynamo driven by the engine. In the last-named case, it is necessary to make a separate determination of the mechanical efficiency of the dynamo, and of any gearing by which it may be driven. The last-named method is generally only to be recommended where the engine and dynamo are directly coupled without intermediate gearing, and the mechanical efficiency of the dynamo may be determined by Hopkinson's two-dynamo method.

A very serviceable transmission dynamometer is described in the early articles, so there is no need to enter into further particulars of this class of test. Absorption dynamometers, or brakes, require some further consideration, however, as they are more commonly adopted in engine testing. It has already been pointed out that unless the brake is suitably designed and rigged on the engine there will be set up frictional resistances which do not occur when the engine is doing its ordinary work. Thus the engine will be unfairly tested. A form of brake which imposes the very minimum of side pressure on the pulley is the strap brake, so arranged as to envelop the pulley almost completely by a strap or set of ropes, and to oppose the tight and slack tensions in the strap in very nearly the same straight line. The side thrust is then reduced to merely the difference between the tight and slack tensions. For small amounts of power, such as in testing gas engines or small steam engines, two or three ropes braced together on the pulley face will serve the purpose; but for large amounts of power a leather belt is better, or a considerable number of large ropes may be used.

If a belt is used, it should be cut into a length slightly less than the circumference of the pulley, and the ends should be fastened securely to lengths of stout cord or wire, according to the stress likely to arise, in the manner shown in Fig. 71. It will be seen that one end is connected to two outer cords, which support a heavy weight from below, while the other end is fastened to the ends of a Y-shaped cord, the upper end of which is secured to a spring balance. It is convenient to fix the spring balance vertically over the pulley to a hook in the roof, or to support it by a cord passing over a fixed pulley. It is usual to arrange that the direction of motion of the engine pulley shall tend to lessen the pull on the spring balance, in which case the reading on this instrument gives the slack tension in the strap, and the pendant weight represents the tight tension. The force of friction resisting the turning of the pulley will, of course, be the difference between these tensions, and the power absorbed will be the product of this resisting force into the linear velocity of the pulley rim. Thus, calling T_2 the tight tension and T_1 the slack tension, and r, N and V the radius in feet, the speed in revolutions per minute and the linear velocity in feet per minute of the pulley, respectively; then we have.

$$\text{B.H.P.} = \frac{(T_2 - T_1)\,V}{33{,}000} = \frac{2\pi r N (T_2 - T_1)}{33{,}000} \quad \ldots . (94)$$

The speed is measured simultaneously with the adjustment of the two tensions, this latter adjustment usually being made by adding or removing weights at the end of the lower cord. It will, of course, be necessary to so adjust matters that the speed is normal.

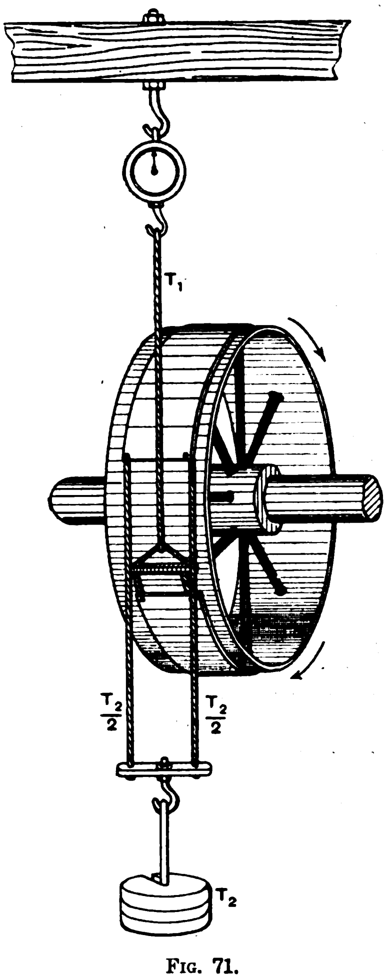

Fig. 71.

As the whole of the power is expended in heating the strap and pulley, it will generally be found necessary to prevent a great rise in temperature by keeping a jet of clean or soapy water playing against the pulley rim and over the strap. This has the further effect of producing a more steady motion, and enables a better adjustment to be obtained; as, if the strap is run quite dry, it is apt to jerk and move irregularly. The use of soapy water, however, often makes these brake tests anything but clean and pleasant.

The brake horse-power and the indicated horse-power of the engine having been determined under the same conditions of working, the mechanical efficiency of the engine will be found by taking the ratio of the former to the latter, and the engine friction by taking their difference.

Test III.

To Determine Steam Consumption when Condensing.—The line of testing which will be adopted in attempting to measure the steam consumption of an engine will depend on whether

Digitized by Google

or no the engine is, or can be, fitted with a surface condenser. We will, in the present case, assume that such a condenser is available. The alternative method is to measure the feed water supplied to the boilers. The chief advantage of the condenser method lies in the fact that the results are not vitiated by the escape of steam, either by condensation or leakage, between the boilers and the engine. The condenser measures the actual steam and water passed into the engine from the steam pipe. It must be observed that it does not distinguish between water supplied as water and water supplied as steam, a distinction which can, however, be made by Test V.

The method of making the test is as follows:—An ample surface condenser, which can be supplied with a copious stream of cold water, is fitted to the engine exhaust, and a pipe leading from the condenser is arranged to convey the condensed steam to a tank which is placed upon a carefully calibrated weighing machine. Care must be taken to see that all the joints are tight, and the condensed steam must be sufficiently cooled by the time it arrives at the weighing tank to prevent any appreciable evaporation or steaming. This done, provision must be made for measuring the steam used in the jackets, if any exist. A short length of glass tube, to act as a gauge glass, is inserted in the end of the jacket drain, and the other end of this glass is connected to a small pipe in which there is a throttle valve. Beyond the throttle valve the pipe passes in a short coil through a cooling tank, and finally discharges the condensed jacket steam into a weighing tank. If a separate determination of the jacket steam is to be made, this weighing tank must be distinct from the main weighing tank.

These preparations completed, the engine must be run for a considerable time under normal conditions, until everything is at a steady condition, before the actual test can be commenced. Steam in the boilers must be kept steady, the supply of condenser circulating water must be regulated, and the throttle valve on the jacket drain must be adjusted until the level of water in the gauge glass is constant. It will take a considerable time to arrive at a sufficiently steady state of affairs; but not until the condensed steam runs into the weighing tank sufficiently cool, and not until the level in the jacket gauge is fairly constant, must any measurement be taken. Keeping the engine on steady load and the steam pressure constant, the test may be commenced at a moment when the tanks are empty, and must be carried on for from half to three-quarters of an hour. The moment of starting the test is noted, and each time the weighing tanks "kick the beam" is also be noted. If the engine is a large one, duplicate tanks may be placed on the weighing machine, and the flow switched alternately to each, thus allowing time to empty the tanks; but in a small test it is sufficient to collect the flow for a moment or two in any convenient small vessel while the tank is being emptied, the small amount collected being afterwards thrown into the tank.

If the steam consumption per horse-power is to be determined, Test I. or II. must be carried on simultaneously with Test III.

(To be continued.)

THE GARE DE SCEAUX CENTRAL STATION.

BY ÉMILE DIEUDONNÉ.

In order to show the important part played by electricity in the working of the extension of the Sceaux line to the Luxembourg, it is necessary to refer to the nature of this extension. The Sceaux railway, which is worked by the Compagnie d'Orleans, penetrates into one of the most densely-populated southern suburbs of Paris. It used to terminate at the Gare de Sceaux, that is to say, about two kilometres from its new terminus. The extension now carried out may be put down as a serious beginning to the long-talked-of metropolitan railway, the various proposals for which have miserably failed and have caused serious injury to Paris. The extension will certainly be carried further, and pushed underground along the Boulevard St. Michel to the Place St. Michel. Further, the Moulineaux line, worked by the Compagnie de l'Ouest—the work upon which is at present being carried out—will be carried past the Champs de Mars to the Invalides, the new terminus being in front of this building. It is, however, permissible to think that things will not long remain in this state, and it will not be long before the line will be continued underground either along the banks of the Seine or along the Boulevard St. Germain, joining the Sceaux extension at the intersection of this boulevard with that of St. Michel or at the Place St. Michel. A few words as to the carrying out of this line. Some 300 metres of the total of 2,000 metres is an open cutting, the remainder being run underground under the public thoroughfare. To carry out this latter work an excavation was first of all opened on one side of the road and one of the abutments was constructed, then the road was opened up and the soil cut away into an arch and bricked over. The abutment on the other side of the street was then constructed, and lastly, the soil was cut away from beneath the brick casing. The distance between the level of the rails and the roadway is approximately 12 metres. The line is run through a part of Paris, the subsoil of which is honeycombed by a network of galleries known as the "catacombs," the tops of which are about 15 metres below the rail level. The trains are worked by means of steam locomotives of a peculiar construction rendered inevitable by the necessity for diminishing smoke and steam as much as possible. The tunnels are well ventilated by means of shafts, and in addition a ventilating tube runs along the top of the roof, terminating in a powerful ventilator worked electrically. The electric plant is particularly interesting, showing as it does the flexibility with which electricity adapts itself to various railway purposes. Besides the electric lighting of the stations at the Luxembourg, Port Royal, and Denfert, and of the Mont Rouge goods yard, which is carried out by 96 arc lamps and 500 glow lamps, there are numerous apparatus worked electrically, such as a ventilator exhausting 180,000 cubic metres of air per hour, a pump, two turn-tables, one turn-bridge, five lifts, and in addition the signals are lit by glow lamps. The Compagnie de l'Ouest asked for tenders from all the best-known electrical concerns of Paris, and the work was given out to the firm of Sautter, Harlé et Cie.

The central station is situated at the side of the Gare Denfert. The boiler plant comprises two Roser multitubular boilers, having 90 square metres (968 sq. ft.) heating surface each, and working at 12 atmospheres (170lb. per square inch) pressure. These boilers are in a well-lit house opening on to the rails, so that the coal is discharged at the foot of the furnaces, thus reducing the manipulation of the fuel to a minimum. The engine room is airy, spacious, and well lit. At present it contains two 120-H P. machines, with room for a third. The engines were made by Chaligny et Cie. These engines, a view of one of which is given in Fig. 1, are compound condensing, driving direct on to the dynamo by means of a belt. The bed-plate is of peculiar construction, with a view to avoiding the necessity of a brickwork foundation. The steam, after leaving the high-pressure cylinder, passes into an intermediate receiver, where it is sensibly heated, and then into the low-pressure cylinder. The steam distribution is effected by means of a simple three-port slide valve, the high-pressure cylinder being regulated by hand, by means of a slide acting on the eccentric. The indicator and steam consumption diagrams of these engines are very interesting and instructive, and it is to be regretted that lack of space does not permit of their publication. These machines have a very workmanlike appearance, and their details seem likely to make them suitable for central station work. The condensers are of the injector type, and are worked by means of an extension of the piston rod of the low-pressure cylinder.

The station being above the catacombs, the sinking of a well for the purpose of obtaining condenser water was out of the question, and water had to be taken from the town mains. The condensing water is cooled by means of the Chaligny cooler, shown in Fig. 2. The cooler consists of a sheet-iron tank erected on a brickwork cement foundation. As will be seen by the illustration, it is provided on one side with a belt-

Digitized by Google

driven air-fan. The tank contains several rows of fascines. The hot water coming from the condenser is forced up by the air-pump to the top of the tank, and distributed over its surface. The water then sinks to the bottom through the fascines, and is thus brought into close contact with the air forced through by the fan. A small portion of this water is evaporated, and in evaporating robs the water of a large amount of heat. The cooled water drains into a masonry tank, and is passed through first a coke and then a sponge filter. The water, thus cooled and purified, is once more ready for condensing purposes. The amount of water evaporating in the cooler is about 8 kilogrammes (17½lb.) per horse-power-hour. About this quantity is furnished by the condensation of the steam, so that it may be said that the consumption of water for condensing purposes is nothing at all. With an apparatus of this kind condensing is no longer limited to places where large quantities of water, amounting to 200 to 300 litres (7 to 10⅓ cubic ft.) per horse-power-hour are available. The dimensions of a cooler of this kind, capable of dealing with an engine of 110 to 170 H.P., are—height, 3·32 metres; breadth, 2·5 metres; depth, 3·95 metres.

the instruments controlling the working of the dynamos, the other dealing with the distribution of the current. The two groups of instruments are mounted on contiguous slate panels, but from the electrical point of view are completely independent. In the diagramatic sketch shown in Fig. 3, I have, with a view of facilitating the understanding of my description, brought the two panels close together, and to the same end I have shown in the same sketch the distributing boards at the Denfert, Port Royal, and Luxembourg stations. At the bottom of the switchboard proper are the + and − bars, on the top the neutral ± bar. An ammeter is placed in the circuit of each dynamo. There are three voltmeters, two of which are constantly in circuit, across each arm of the three-wire circuit; the third, which is a dead-beat instrument, is intended by means of a switch to enable the engineer to ascertain the pressure on the mains and that between the terminals of the dynamo which it is proposed to switch into use.

The electromagnetic circuit cut-outs I *m* play an important part in switching the dynamos in and out of circuit; they are so arranged that it is impossible to switch into circuit a dynamo which is not at the same pressure as those already at

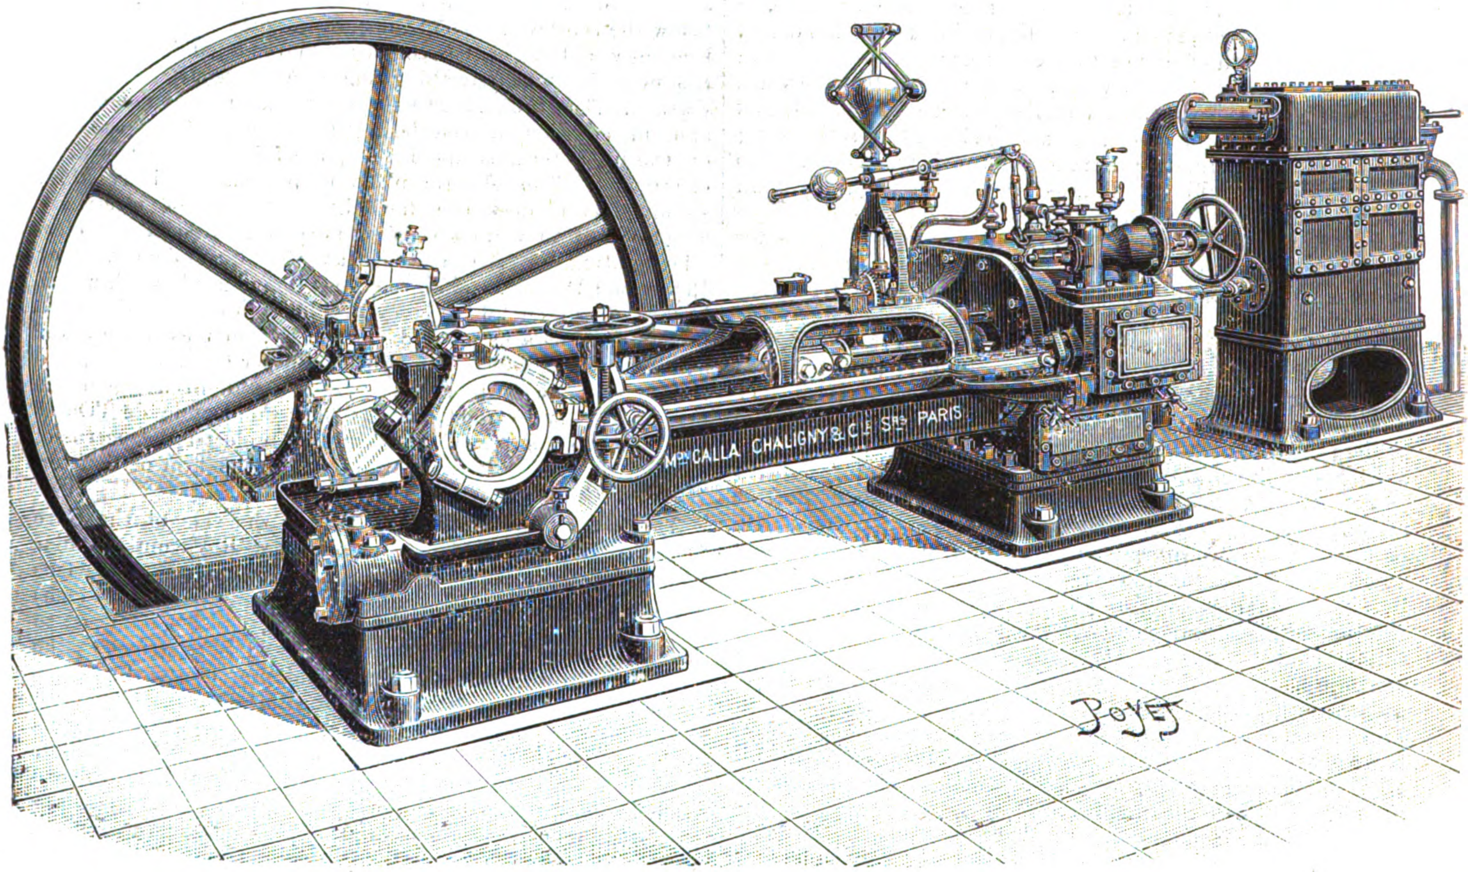

FIG. 1.—Chaligny Compound Condensing 120 H.P. Engine.

The dynamos are double-armature machines, with two distinct fields, and revolve at 420 revolutions per minute. Each armature at full load supplies 160 amperes at 270 volts. The dynamo pulley is keyed on to the dynamo shaft midway between the two armatures. The distribution takes place on the three-wire system at a pressure of 220 volts on each arm, arc lamps being run four in series and glow lamps two in series. Two batteries of accumulators—one at the central station and the other at the Gare du Luxembourg—supply the current to the electric motors driving the turn-tables and lifts; these batteries also supply the current to the glow lamps during the hours when the station is shut down. The arrangement of the plant contemplates the use of parallel running, but at present the dynamos are only paralleled at the moment of switching in or out of circuit; but later on, when the line has been extended, parallel running will be the normal order of proceeding. The apparatus on the station switchboard is divided into two distinct groups, one comprising

work, and they automatically switch the dynamo out of circuit when its current falls below a certain figure. The apparatus, which is shown in Fig. 4, consists of a lever L capable of completing the circuit between the jaws M and M_1, and of an arrangement of coils actuating the interlocking mechanism. Knowing by the dead-beat voltmeter the pressure on the mains and the voltage of the dynamo to be switched in, one knows in what direction it is necessary to alter the field-magnet resistance to bring the two to an equality. When this has been done the two sets of electro-magnets, E E and F F, the pull of which is exerted in opposite directions, liberate the arm m_1, which locks the lever L. It will be seen that the coils E E and F F are circuited between the neutral wire, to which the thin bar, shown dotted in the sketch, is connected, and the + pole of the machine which is to be switched in, whilst the coils F F are between the + pole of the network and the neutral wire, the terminal B being connected to the corresponding pole of the dynamo and the terminal B_1 to the general posi-

tive bar. One can see that when the two pressures are equal the actions of the electro-magnets E E and F F neutralise each other and liberate the bar m_1. The circuit can then be closed the bar *m* clutches the lever L. When, owing to some cause or other, the current of the dynamo is reduced to a certain amount, it is necessary that it should be put out of circuit. This

by means of the lever L. The current then passes through the coils of the electro-magnets C C, and the pendulum *p* polarised by the electro-magnet A is diverted from its vertical position, the circuit of the electro-magnet D is broken, and is accomplished automatically. The magnetism of the electro-magnets C C decreasing with the current, the pendulum *p* tends to resume its vertical position, and at a certain point it makes contact with the terminal *b*. The circuit of the coils

D D is completed, the arm *m* is attracted, and the lever L is free, and is shot away from M M_1 by the action of a powerful spring, and the dynamo is switched out of circuit.

The distribution board is next to the switchboard, properly speaking, and from it run the circuits to the various stations on the line and to the signal lamps. The omnibus bars on the distributing board are connected to those on the switchboard, through recording ammeters. As will be seen from the sketch, this board is provided with pressure indicators, P; these give warning to the central station engineer, acoustically and optically, whenever the pressure at the various stations is not at its normal value. This is done without pilot wires, by using compound-wound instruments. The boards at the various stations, as will be seen from Fig. 3, are provided with switches

so arranged that in one position the current is sent through an ammeter, and in another straight to the lamps; in the third the circuit is broken. The voltmeters are always in circuit.
